MATANUSKA-SUSITNA BOROUGH
PLANNING COMMISSION AGENDA

Vern Halter, Mayor

PLANNING COMMISSION
Mary Anderson, District 1
Thomas Healy, District 2
John Klapperich, Chair, District 3
Colleen Vague, District 4
William Kendig, District 5
Tomas Adams, District 6
Vern Rauchenstein, District 7

John Moosey, Borough Manager

PLANNING & LAND USE DEPARTMENT
Eileen Probasco, Director of Planning & Land Use
Sara Jansen, Acting Planning Services Chief
Alex Strawn, Development Services Manager
Fred Wagner, Platting Officer
Mary Brodigan, Planning Clerk

Assembly Chambers of the
Dorothy Swanda Jones Building
350 E. Dahlia Avenue, Palmer

November 7, 2016
REGULAR MEETING
6:00 p.m.

I. CALL TO ORDER, ROLL CALL, AND DETERMINATION OF QUORUM

II. APPROVAL OF AGENDA

III. PLEDGE OF ALLEGIANCE

IV. CONSENT AGENDA

Items on the consent agenda are considered to be routine and non-controversial by the Commission and will be approved by one motion. There will be no separate discussion of these items unless a Commission Member so requests, in which case the item will be removed from the Consent Agenda and considered in its normal sequence on the agenda.

A. MINUTES
1. August 15, regular meeting minutes

B. INTRODUCTION FOR PUBLIC HEARING: QUASI-JUDICIAL MATTERS
1. A remand to the Planning Commission for further consideration of the Central Monofill Services (CMS) application for a Conditional Use Permit under MSB Code 17.60, for the operation of a monofill for the disposal of inert construction and demolition debris, including regulated asbestos-containing material (RACM) and non-regulated asbestos-containing material (non-RACM), and an outdoor storage yard for the sale of salvageable/recyclable materials, located at 2840 S. Glenn Highway (Tax ID: 17N02E18C010) AND 2560 S. Glenn Highway (Tax ID: 17N02E19B006); within Township 17 North, Range 2 East, Sections 18 and 19, Seward Meridian. Public Hearing: December 5, 2016. (*Applicant: Central Monofill Services (CMS), Staff: Mark Whisenhunt*)

C. INTRODUCTION FOR PUBLIC HEARING: LEGISLATIVE MATTERS

V. COMMITTEE REPORTS

VI. AGENCY/STAFF REPORTS

VII. LAND USE CLASSIFICATIONS

VIII. AUDIENCE PARTICIPATION (*three minutes per person, for items not scheduled for public hearing*)

IX. PUBLIC HEARING: QUASI-JUDICIAL MATTERS (*Public Hearings shall not begin before 6:15 p.m.)*

Commission members may not receive or engage in ex-parte contact with the applicant, other parties interested in the application, or members of the public concerning the application or issues presented in the application.

The Planning Commission members may submit questions to the Planning Commission Clerk concerning the following matters or request for more information from the applicant at the time of the introduction. All questions and requests submitted by the Commission shall be in writing and copies will be provided to the applicant and made available to all interested parties and the public upon request. Answers to questions and additional material requests will be addressed in the staff report for the public hearing.

A. **Resolution 16-37**, a request for a Conditional Use Permit in accordance with MSB 17.70, Regulation of Alcoholic Beverage Uses, for the operation of an alcoholic beverage dispensary (bar) at the 907 Club, located at 2541 S. Rosalie Court; MSB Tax ID# 5428000T00A; within Township 17 North, Range 3 West, Section 21, Seward Meridian. (*Applicant: Mark Button, dba RMB, LLC, 907 Club, Staff: Mark Whisenhunt*)

X. PUBLIC HEARING: LEGISLATIVE MATTERS

A. **Resolution 16-40**, A resolution recommending Assembly approval of an ordinance amending MSB 15.24.030(5) and adopting the City of Houston's Comprehensive Plan Update. (*Staff: Van Le, R&M Consultants)*

XI. CORRESPONDENCE & INFORMATION

XII. UNFINISHED BUSINESS

XIII. NEW BUSINESS

XIV. COMMISSION BUSINESS

A. MSB Board of Ethics Advisory Opinion 16-01

B. Correction to Code Reference in Planning Commission Resolutions 16-30, 16-31, and 16-32

C. Upcoming Planning Commission Agenda Items (*Staff: Eileen Probasco*)

XV. DIRECTOR AND COMMISSIONER COMMENTS

XVI. ADJOURNMENT (Mandatory Midnight)

In order to be eligible to file an appeal from a decision of the Planning Commission, a person must be designated an interested party. See MSB 15.39.010 for definition of "Interested Party." The procedures governing appeals to the Board of Adjustment & Appeals are contained in MSB 15.39.010-250, which is available on the Borough Internet home page, http://www.matsugov.us, in the Borough Clerk's office, or at various libraries within the Borough.

Disabled persons needing reasonable accommodation in order to participate at a Planning Commission Meeting should contact the borough ADA Coordinator at 861-8432 at least one week in advance of the meeting.

MINUTES
August 15, 2016

(Page 5 - 20)

MINUTES

The regular meeting of the Matanuska-Susitna Borough Planning Commission was held on August 15, 2016, at the Matanuska-Susitna Borough Assembly Chambers, 350 E. Dahlia Avenue, Palmer, Alaska. The meeting was called to order at 6:00 p.m. by Chair John Klapperich.

I. CALL TO ORDER, ROLL CALL, AND DETERMINATION OF QUORUM

Planning Commission members present and establishing a quorum:
Ms. Mary Anderson, Assembly District #1
Mr. Thomas Healy, Assembly District #2
Mr. John Klapperich, Assembly District #3 *Chair*
Ms. Colleen Vague, Assembly District #4
Mr. William Kendig, Assembly District #5
Mr. Vern Rauchenstein, Assembly District #7

Planning Commission members absent and excused were:
Mr. Tomas Adams, Assembly District #6

Staff in attendance:
Mr. Alex Strawn, Development Services Manager
Mr. John Aschenbrenner, Deputy Borough Attorney
Ms. Susan Lee, Planner II
Ms. Mary Brodigan, Planning Commission Clerk

II. APPROVAL OF AGENDA

Chair Klapperich inquired if there were any changes to the agenda.

GENERAL CONSENT: The agenda was approved without objection.

III. PLEDGE OF ALLEGIANCE

The pledge of allegiance was led by Mr. Douglas Clegg, a member of the audience.

IV. CONSENT AGENDA

A. Minutes

1. August 1, 2016, regular meeting minutes

A. INTRODUCTION FOR PUBLIC HEARING: QUASI-JUDICIAL MATTERS

1. **Resolution 16-30**, a Conditional Use Permit (CUP) in accordance with MSB 17.67 – Tall Structures including Telecommunication Facilities, Wind Energy Conversion Systems, and Other Tall Structures, for a 180 foot tall telecommunication tower (NSL1), located at 23619 W. Parks Highway; MSB Tax ID # 18N04W11A001; within Township 18 North, Range 4 West, Section 11, Seward Meridian. Public Hearing: September 19, 2016. (*Staff: Mark Whisenhunt*)

DRAFT

2. **Resolution 16-31**, a Conditional Use Permit (CUP) in accordance with MSB 17.67 – Tall Structures including Telecommunication Facilities, Wind Energy Conversion Systems, and Other Tall Structures, for a 180 foot tall telecommunication tower (DLY1), located at 41238 W. Parks Highway; MSB Tax ID # 20N04W06C003; within Township 20 North, Range 4 West, Section 6, Seward Meridian. Public Hearing: September 19, 2016. (*Staff: Mark Whisenhunt*)
3. **Resolution 16-32**, a Conditional Use Permit (CUP) in accordance with MSB 17.67 – Tall Structures including Telecommunication Facilities, Wind Energy Conversion Systems, and Other Tall Structures, for a 180 foot tall telecommunication tower (KSH1), located at 15960 E. Kashwitna Road; MSB Tax ID # 23N04W29C006; within Township 23 North, Range 4 West, Section 29, Seward Meridian. Public Hearing: September 19, 2016. (*Staff: Mark Whisenhunt*)

C. NTRODUCTION FOR PUBLIC HEARING: LEGISLATIVE MATTERS

1. **Resolution 16-27**, recommending Assembly adoption of the FY 2018 – 2023 Capital Improvement Program. Public Hearing: September 19, 2016. (*Staff: Sara Jansen*)

Chair Klapperich read the consent agenda into the record.

Chair Klapperich inquired if there were any changes to the consent agenda.

GENERAL CONSENT: The consent agenda was approved without objection.

V. COMMITTEE REPORTS

(There were no committee reports.)

VI. AGENCY/STAFF REPORTS

(There were no agency/staff reports.)

VII. LAND USE CLASSIFICATIONS

(There were no land use classifications.)

VIII. AUDIENCE PARTICIPATION (Three minutes per person.)

The following persons spoke in protest of the proposed Central Monofill Services facility: Ms. Rose Williams, Mr. Eric Bleakney, Ms. Geri McCann, Ms. Stephanie Nowers, Ms. Barbara Landi, Mr. Chris Kepler, Mr. Nicholas McGrath, Ms. Janet McGrath, Ms. Stephanie Figon, Mr. Tony Sellen, and Mr. William Quantick.

The following persons spoke regarding the Colony Skilled Nursing Facility: Mr. Douglas Clegg and Mr. Donald Dyer.

The following person spoke regarding concerns with public process: Mr. Eugene Carl Haberman.

DRAFT

IX. PUBLIC HEARING: QUASI-JUDICIAL MATTERS *(Public Hearing not to begin before 6:15 P.M.)*

Commission members may not receive or engage in ex-parte contact with the applicant, other parties interested in the application, or members of the public concerning the application or issues presented in the application.

(There were no quasi-judicial public hearings.)

X. PUBLIC HEARING LEGISLATIVE MATTERS

A. **Resolution 16-28,** recommending Assembly approval of an Interim Materials District (IMD) known as Denali Highway Mile 99, in accordance with MSB 17.28 – Interim Materials District, for the extraction of 500,000 cubic yards of earth material within a 69.91 acre parcel until the year 2060, located within Township 19 South, Range 2 West, Section 10 & 15, Fairbanks Meridian. (*Applicant: State of Alaska, Department of Transportation and Public Facilities, AKDOT&PF, Staff: Susan Lee*)

Chair Klapperich read the resolution title into the record.

Ms. Susan Lee provided a staff report:
- staff recommended approval of the resolution with conditions.

Commissioners questioned staff regarding clarification of the size of the cells as shown on page 367 of the packet.

Mr. Henry Cole, Alaska Department of Transportation and Public Facilities (AKDOT&PF), provided an overview of their application via teleconference.

Commissioners questioned Mr. Cole regarding:
- whether there are other sources of gravel in the area; and
- will this IMD change the way the highway is used.

Chair Klapperich opened the public hearing.

The following person spoke regarding concerns with public process: Mr. Eugene Carl Haberman.

There being no one else to be heard, Chair Klapperich closed the public hearing and discussion moved to the Planning Commission.

Chair Klapperich offered Mr. Cole the opportunity to respond to questions and comments from members of the audience.

Mr. Cole responded to questions and comments from a member of the audience.

MOTION: Commissioner Healy moved to approve Resolution 16-28. The motion was seconded.

DRAFT

MOTION: Commissioner Rauchenstein moved a primary amendment to add an additional condition to read: "The owner shall apply for a driveway permit prior to constructing a second driveway." The motion was seconded.

Deputy Attorney Aschenbrenner stated that this is a state road and the applicant, the State of Alaska, would not apply for a driveway permit with the Borough.

Mr. Cole:
- stated that there currently are no driveways in existence;
- for DOT to put in a driveway from a DOT road to a DOT material site would consist of sending a drawing of the proposal to our traffic engineer who will make sure that it complies with site distance requirements and dimensions;
- stated the AKDDOT does not require permits from themselves, and
- if and when they do construct a driveway, they will hold it to the same standards that they require of commercial businesses, contractors, and homeowners.

WITHDRAWN: Commissioner Rauchenstein withdrew his primary amendment.

There was no objection noted.

VOTE: The main motion passed without objection.

XI. CORRESPONDENCE AND INFORMATION

A. Superior Court Order Remanding the Planning Commission's Denial of CMS's Permit
B. Ethics Board Advisory Opinion 15-01

Chair Klapperich read the item into the record.

Mr. Alex Strawn:
- provided an overview of the events leading up to these agenda items;
- stated that he will be making a recommendation to the commission as to how he thinks that they should proceed with the recusal of Commissioner Kendig and the Conditional Use Permit (CUP) application for Central Monofill Services (CMS);
- recommended that the commission also give CMS the opportunity to state how they think the commission should proceed;
- noted that there was a procedural error with the way that Commissioner Kendig was recused, and for that reason, the CUP was remanded back to the commission by Alaska Superior Court;
- the Superior Court ordered that the commission revisit the recusal of Commissioner Kendig and then revisit CMS's application;
- recommended that the commission first afford Commissioner Kendig the opportunity to state his position on whether or not he should recuse himself;
- if Commissioner Kendig does not choose to recuse himself, the commission will need to take up the matter of his recusal;

DRAFT

- the decision on whether to recuse Commissioner Kendig needs to be addressed first because if he is to be recused, he will not be able to participate in the proceedings;
- suggested that in this case they should review the transcripts for the previous meetings dealing with this issue, the information within the record, and the facts surrounding the recusal;
- the commission may also wish to request additional information to explore some of the facts around the case;
- stated that the next few PC meetings are already pretty full with towers, variances, and liquor stores;
- opined that November would be the earliest that a public hearing could be scheduled for this item;
- noted that the record will be large and the PC will need to act as a whole; and
- new commissioners will need to get caught up in order for the commission to make a new decision and to adopted findings of fact and conclusions of law to support the decision.

Chair Klapperich requested that both Mr. Aschenbrenner and Mr. Ingaldson explain to the Planning Commission how they think the commission should proceed regarding the recusal of Commissioner Kendig and the public hearing for CMS.

Mr. John Aschenbrenner, Deputy Borough Attorney:

- clarified that the court did not reverse the decision of the Planning Commission, but vacated the decision at the point where the commission took up the question of Commissioner Kendig's recusal;
- stated that there is currently no decision regarding CMS's application for a CUP;
- after the commission rendered its decision, Commissioner Kendig sought an ethics opinion on whether he should sit during a legislative item for an Assembly ordinance that would affect the ability of applicants like CMS to seek a permit within the core area;
- in the process of rendering a decision on the legislative item, the Ethics Board found that Commissioner Kendig had been appropriately recused on CMS's application for a CUP;
- opined that the commission has before it the task of determining if Commissioner Kendig should sit;
- the court also conveyed that it was the appropriate decision that Commissioner Kendig not vote on his recusal;
- Mr. Kendig can choose to recuse himself, in which case the commission will not have to take up the matter collectively;
- if he does not choose to recuse himself, the commission will have to address the matter;
- the two new commissioners will need to review the record and he urged the rest of the commission to familiarize themselves with it as well;
- in addition to vacating the decision, the court ruled that it will be appropriate to hold a hearing;
- opined that because the commission is back at the beginning before the previous public hearing, the hearing the court was contemplating was another public hearing before this body;
- stated that the court noted that if the matter isn't resolved under MSB 2.71.080 Recusal, the commission will have to take up 2.71.070(A)(2)(d), *A municipal official may not take or withhold official action in order to affect a matter in which the municipal official has a*

DRAFT

substantial financial interest or 15.08.150(A) *shall not participate in deliberation or vote on a question if* (1) *the commission member or a member of the commission member's immediate family has a substantial financial interest in any property affected by the decision or* (2) *could foreseeably profit in any material way through a favorable or unfavorable decision*;

- if Commissioner Kendig does not recuse himself, additional information will need to be elicited from him since MSB 2.71.080 is fairly clear that an official must recuse themself if there has been a transaction that has occurred within 12-months of the matter:
  - what was the nature of the transaction that occurred between Commissioner Kendig and the individuals that are seeking this permit from the borough;
  - what was the nature of the conversation that members of the public witnessed after Commissioner Kendig recused himself and then took a seat in the audience;
  - commissioners will need to look at this information with regards to MSB 15.08.150 Conflict of Interest;
- the court made it clear that the commission must provide findings of fact not only on the recusal, but on the merits of the application;
- following a decision on a recusal and the public hearing, both sides can provide findings of fact, but the prevailing side is required to provide findings of fact; and
- stated that it is important to give the court the underlying rationale for a decision.

Chair Klapperich queried Mr. Aschenbrenner as to what he would like the Planning Commission to do tonight.

Mr. Aschenbrenner:

- questioned if Commissioner Kendig intends to recuse himself tonight;
- noted that Commissioner Kendig has an ethics opinion from the MSB Board of Ethics stating that he was properly recused from the original hearing;
- if Commissioner Kendig does not recuse himself, both he and Mr. Ingaldson concur that the verbiage should be "should Commissioner Kendig be recused from this matter" rather than "should he continue to sit";
- the second statement was in the negative and leaves a question as to the outcome; and
- opined that the commission had the correct outcome, but unfortunately the question was framed incorrectly.

Mr. Bill Ingaldson, Attorney representing CMS:

- stated the he and Mr. Aschenbrenner agree on some things, but not on other things;
- opined that the ethics opinion was part of the appeal and that the judge was aware of it;
- one of the arguments advanced by the borough is that even if there was a mistake with parliamentary procedure, the right result happened as confirmed by the ethics opinion;
- stated that this argument was rejected by the judge;
- CMS was not part of that particular ethics opinion and was unaware of it until recently;
- noted that even an ethics opinion is subject to appeal;
- the PC can consider this ethics opinion, but opined that it's not binding;
- stated that his appeal to superior court on behalf of CMS was to overturn the recusal of Commissioner Kendig;

DRAFT

- Judge Smith rejected this argument and agreed with the borough that the decision had to be vacated;
- the commission will need to look at this from the perspective of now;
- a commissioner that may not have had a conflict back then, but may have one now;
- agreed with Mr. Aschenbrenner that the question of recusal was framed wrong;
- the question should have been, "should Commissioner Kendig be recused";
- Commissioner Kendig was not allowed to vote and so the vote came down to four people and it took four votes to take action;
- opined that it takes a majority vote and not four affirmative votes;
- stated that the court agreed that it should have been a majority vote;
- Commissioners Healy, Klapperich, and Rauchenstein voted that they thought that Commissioner Kendig could be fair, and Commissioner Endle voted "no";
- noted there was one sale of some scrap metal for less than $1,000 and questioned whether this would make Commissioner Kendig a client;
- opined that this is a vague area;
- respectfully disagreed that and suggested that Judge Smith disagreed as well;
- opined that the issue is "can Commissioner Kendig be fair";
- stated that going forward procedurally, one of the commissioners will have to bring a motion to recuse Commissioner Kendig unless he should choose to recuse himself for some reason;
- there will have to be a majority vote to recuse him and there will have to be a basis for the recusal;
- noted that there was a member of the Board of Adjustment and Appeals (BOAA) that divulged that he had done surveys for many of the people that live in that area;
- when asked if he could still be fair, he stated that he could;
- at the time of the first public hearing, Commissioner Healy worked for the City of Palmer and the City Mayor and Manager spoke against this application;
- stated that he has known Commissioner Healy on a professional level for a number of years and does not believe that he would make a decision based on what his employer said;
- suggested that the commission needs to afford Mr. Kendig the same courtesy;
- opined that if someone is recused, that is an automatic negative vote;
- agreed that the commission's first step is to address the issue with Commissioner Kendig;
- suggested that if he hasn't had any recent dealings with CMS, that will be the end of it unless someone else has another reason for him to be recused;
- acknowledged that Mr. Kendig spent a lot of time reviewing the packet the last time, and because he sold scrap metal for less than $1,000, he could not sit on this item;
- if this is something that the commission feels is unfair, then someone should make the motion to recuse Commissioner Kendig which will require a second and a vote;
- stated that he has heard hearsay comments and accusations that Commissioner Kendig was seen talking to CMS;
- his clients have denied speaking to Commissioner Kendig;
- acknowledged that during a break, Commissioner Kendig did approach him and started to speak, but he immediately cut him off saying "we can't talk;"
- stated that they separated with no discussion;
- the process needs to be fair going forward for everyone including property owners and the applicants;

DRAFT

- since the decision has been vacated, everyone will have to go through the whole thing again and he would prefer to have seven commissioners sitting rather than six; and
- reminded the commissioners that all commissioners will have to go through the same process to determine if they have a potential conflict.

Mr. Aschenbrenner:
- stated that Mr. Ingaldson conveyed that the court rejected the Borough's argument that it could ignore the procedural motion and in the same sentence he brought up that the court had rejected the ethics complaint;
- stated that this is absolutely wrong;
- there was no reference in the court's decision regarding the ethics opinion;
- the court just didn't take it up;
- the Board of Ethics received their authority from the MSB Assembly to decide questions of ethics;
- the commission has a decision by that body conveying that Commissioner Kendig was properly recused;
- opined the idea that the court rejected the ethics opinion is flatly wrong; and
- stated that this will not be a new application, but the same application.

Mr. Ingaldson:
- agrees with Mr. Aschenbrenner that the ethics opinion is not referenced in the court decision, but implicit in his ruling is that it was rejected;
- stated that he will be happy to provide the commission with the briefing on this issue;
- emphasized that the defense brought up by the borough was that it doesn't matter that there was a procedural error because the ethics opinion determined that Mr. Kendig was appropriately recused;
- stated that the court rejected that argument or they wouldn't be here on this issue today;
- opined that the court wouldn't send anything back to vote on it if they didn't think that he deserved to be here;
- stated that it's not in the decision, but a lot of the things aren't in the decision; and
- implicit in that decision necessarily is that Judge Smith isn't going to make you do all do a bunch more work for nothing.

Commissioner Kendig:
- stated that he has a lot of questions before he makes a decision;
- heard that there will be a new public hearing, but is not clear if it will be the same application; and
- queried the borough attorney if the timeline will remain the same since so much time has passed.

Mr. Strawn stated that it will be the same application.

Mr. Aschenbrenner:
- the timeline remains the same;
- stated that it would be turning borough code on its head to say that an individual commissioner can sit as long as enough time goes by on an individual application;

DRAFT

- this is the argument of CMS; and
- it is wrong to interpret borough code in the way that CMS is seeking, and opined that it makes no sense.

Chair Klapperich:
- stated that he had said that there wouldn't be any action tonight since there isn't an official public hearing; and
- prefers that Commissioner Kendig does not state his position tonight.

Commissioner Kendig:
- stated that he is as astounded about all of the this as anyone else;
- noted that it hasn't been any fun sitting in the hot seat;
- he takes his position on the commission very seriously, and wants without a shadow of a doubt to make the right decision;
- noted that Assemblymembers have in the past asked for a second opinion from a neutral party and is asking for the same;
- stated that he will be asking for another opinion from the Board of Ethics as he believes that this is a little bit of a different situation; and
- he would also like an opinion from an outside law firm.

Mr. Aschenbrenner:
- stated that the Board of Ethics is the second opinion;
- the ethics opinion addressed that Commissioner Kendig was properly recused;
- it does not address the various borough ordinances that will also have a bearing on whether or not he should sit;
- stated that there isn't anything to prohibit him from seeking another opinion from the Board of Ethics in the interim between this date and the date that the matter is set for a future public hearing;
- borough staff does not object to Commissioner Kendig seeking another opinion, but urges him to provide enough information to the board so that they can render a decision on those additional ordinances; and
- stated that even if Commissioner Kendig seeks an opinion from an outside attorney, the final authority is with the Board of Ethics.

Chair Klapperich:
- clarified that there will not be a public hearing regarding Commissioner Kendig's recusal;
- this will be an individual and Planning Commission decision only; and
- stated that there will be a new public hearing even though it is the same application that came before the commission previously.

Mr. Aschenbrenner:
- would like to note for the record, as he did in the original hearing, that anyone can appeal the final decision of the Planning Commission including interested parties, members of the public, and staff;
- if there is an error built into the record with regard to who is sitting, they will have an opportunity to appeal the decision based on that question;

DRAFT

- this was noted in the courts decision; and
- while there won't be a separate public hearing regarding Mr. Kendig's recusal, it's clear that members of the public would have an opportunity to appeal the decision based on that question.

Mr. Ingaldson:
- stated that there is a lot of case law in Alaska regarding recusals;
- there has to be a legitimate reason for a recusal and it cannot be done lightly;
- judges that have tried to recused themselves have had their recusals overturned;
- the reason is that the public has the right to have a full panel whenever possible;
- there must be a serious reason to recuse yourselves;
- stated that he would agree with Mr. Aschenbrenner that if we were not having a new public hearing, we would go back to voting as it was at that time;
- this is what we urged the court to do, but they rejected it;
- you will have to go back a year from now and if one of you has a conflict that you didn't have before, you won't be able to sit;
- Commissioner Kendig's transaction was over two years ago with less than a $1,000 purchase;
- our position is that it was not a violation anyway;
- reminded the commission that an ethics opinion can be appealed;
- if you say that one of you should be recused because of this ethics opinion, we will be right back here because Judge Smith's decision is irreconcilable with that finding; and
- opined he would not be here asking commissioners to vote if, as a matter of law, Mr. Kendig should have recused himself.

Discussion ensued amongst the commission as to how to proceed.

Mr. Aschenbrenner:
- when the court vacated the decision, Judge Smith remanded it with the understanding that the matter was placed back before the commission at the point in time that the board took up who should sit on the matter;
- the appellant argued that Mr. Kendig's absence from the board was prejudicial to them;
- opined that to a certain extent the court agreed in the sense that it vacated the final decision and put it back before the board at the point in time that Commissioner Kendig's recusal was taken up by the commission;
- the vacation is of the final order, but the commission will still need to consider the entire record;
- the record will consist of everything that existed at the point in time where the commission took up the recusal question along with the transcript of the public hearings and anything new that comes before the commission before and during the new public hearing; and
- the commission will have to render a decision based on all of this information.

Mr. Ingaldson:
- stated that it is their position that there should be a vote on Mr. Kendig, after which he could review the record, and everyone else wouldn't have to go through this again;

DRAFT

- Mr. Aschenbrenner argued that people have the right to have a hearing and Judge Smith agreed with him on that;
- concurred that the order is clear that the hearing was vacated;
- acknowledged that if the borough has new evidence, the commission will get to hear it;
- similarly, if CMS has new information, the commission will get to hear that as well;
- disagrees with Mr. Aschenbrenner on one point;
- the commission does not get to go back right to the spot to make it convenient to recuse Commissioner Kendig;
- everyone has worked very hard on this and deserves some finality, but everyone also deserves to have a fair hearing;
- stated that he will be happy to meet with Mr. Aschenbrenner about the scope of where to go and opines that they can come to some agreement of what they can or cannot consider; and
- very much appreciates that Mr. Aschenbrenner has been kind enough to urge the commission to listen to him.

Chair Klapperich queried the commission as to how they would like to wrap things up tonight.

Commissioner Vague:
- stated that she has known Mr. Kendig for more than ten years;
- acknowledged that Mr. Kendig brought this subject up to her in a private conversation that came up before she was given this information;
- queried whether this was ex parte communication and if she will need to recuse herself if the commission has to vote on whether or not to recuse Mr. Kendig;
- stated that she felt like she was being swayed to vote one way or another regarding a recusal; and
- until she got the packet a few days later, she didn't know what Mr. Kendig was talking about.

Mr. Aschenbrenner:
- ex parte contact contemplates a communication between a commissioner and one side;
- opined that this does not meet the definition of ex parte contact;
- thanked Commissioner Vague for disclosing this information;
- stated that the Borough Attorney's Office, on behalf of staff, does not object to Commissioner Vague sitting; and
- recommended that the commission allow Mr. Ingaldson to weigh in.

Mr. Ingaldson:
- stated that he has no objection to Commissioner Vague sitting;
- noted that no one has made a motion to recuse yet; and
- if Commissioner Vague wishes, she can abstain from voting on the recusal.

Chair Klapperich:
- requested clarification that if Commissioner Kendig chooses to recuse himself, the commission will not have to vote on his recusal; and

DRAFT

- if Commissioner Kendig does not recuse himself, the commission will need to vote on whether he should be recused.

Mr. Ingaldson:
- stated that if Commissioner Kendig does not recuse himself, then he sits unless a commissioner moves to recuse him; and
- the motion will need to be seconded and then there will be a vote.

Chair Klapperich queried the commission as to what they would like to accomplish tonight.

Commissioner Healy:
- suggested that the commission schedule a public hearing for some time in November or December to provide adequate public notice;
- the borough will provide the packet with all of the information that has been considered previously; and
- the recusal issue can be brought up again just prior to the public hearing.

Discussion ensued:
- possible dates for the public hearing;
- the commission prefers not to schedule a public hearing on November 7th as only half of the Assembly Chambers will be available due to the November 8th election;
- possibly moving the November 7th meeting to November 14th;
- the potential for scheduling conflicts in December due to the holidays; and
- limiting the agenda to the one public hearing for CMS.

Commissioner Kendig stated that he has a conflict on November 14th and is not available.

The commission requested that Ms. Brodigan schedule the public hearing for a date other than November 7 or 14, 2016.

[Clerk's note: the introduction for CMS has been scheduled for November 7, 2016, with the public hearing on December 5, 2016.]

(Commission Business was presented and no comments were noted.)

DRAFT

XV. DIRECTOR AND COMMISSIONER COMMENTS

Ms. Brodigan:

- stated that there are a couple of updates for code books; and
- requested commissioners bring in their code books if they would like them updated prior to the next few meetings.

Commissioner Anderson:

- thanked everyone for coming out tonight to listen to the proceedings and to weigh in;
- thanked Mr. Aschenbrenner and Mr. Ingaldson for bringing commissioners up to speed;
- stated that she is new and acknowledged that this will be a challenge, but opined that she is up to the task;
- thanked her fellow commissioners for their patience once again;
- acknowledged that sometimes issues like this come back and it takes a bit of time to get up to speed; and
- opined that the commission will come up with a good decision.

Commissioner Vague:

- stated that she has known Commissioner Kendig for years and would like to make it clear that she has the utmost respect for him;
- opined that he will do what it right for himself, everyone else on the board, and for the community;
- stated that she did not mean to imply anything otherwise, other than she wanted to do the right thing; and
- opined that the code word for the day is to be very transparent.

Commissioner Healy stated that he will be out of state during the September 19th and October 3rd meetings, and asking to be excused.

Chair Klapperich:

- stated that he wants the applicant to feel very confident regarding Commissioners Vague and Anderson regarding their professionalism and preparedness;
- noted that Ms. Vague provided great leadership on the school board for many years;
- Ms. Anderson, wife of former Mayor Anderson certainly knows what is going on;
- opined that they come very well educated and prepared;
- Mr. Adams will lend good credence as well;
- opined that sometimes getting it right takes a little extra effort; and
- stated that as chairman of this commission, he takes public process very seriously.

MEMORANDUM

DATE: October 24, 2016

TO: Planning Commission

FROM: Alex Strawn, Development Services Manager

SUBJECT: Content of the Packet for Remand of Central Monofill Services' Request for Junkyard/Refuse Area Conditional Use Permit

The Superior Court for the State of Alaska has ordered the Planning Commission's decision to deny Central Monofill Services (CMS) conditional use permit be reversed and the case be remanded back to the Planning Commission. CMS had submitted a conditional use permit under MSB 17.60 – Conditional Uses, for the operation of a monofill for the disposal of inert material. The debris will primarily be non-hazardous shredded material from construction and demolition waste, including Regulated Asbestos Containing Material (RACM) and Non-RACM material. The proposed site is located on MSB Tax Parcels: 17N02E18C010 (2840 S. Glenn Highway) and 17N02E19B006 (2560 S. Glenn Highway); within Township 17 North, Range 2 East, Sections 18 and 19, Seward Meridian.

The content of the packet consists of the following items:

1. Superior Court Orders
2. Planning Commission Resolution 15-01 Supporting Denial of 14-33
3. Board of Adjustment and Appeals Order 15-01
4. Board of Ethics Advisory Opinion 16-01
5. Board of Ethics Advisory Opinion 15-01
6. Packet Related to Planning Commission Resolution 14-33
7. Handout Documents Related to Planning Commission Resolution 14-33
8. Packet Related to Planning Commission Resolution 15-01
9. Planning Commission Minutes for December 1, 2014
10. Planning Commission Minutes for December 15, 2014
11. Planning Commission Minutes for January 5, 2015
12. Transcript for Planning Commission Meeting December 1, 2014
13. Transcript for Planning Commission Meeting December 15, 2014

IN THE SUPERIOR COURT FOR THE STATE OF ALASKA

THIRD JUDICIAL DISTRICT AT PALMER

CENTRAL MONOFILL SERVICES, INC. Appellant, vs. MATANUSKA-SUSITNA BOROUGH BOARD OF ADJUSTMENTS, Appellee.	CASE NO. 3PA-15-01925 CI

ORDER

The Matanuska-Susitna Borough Board of Adjustments filed a Limited Motion to Reconsider, asking the court to reconsider its July 5, 2016 order as to the number of votes necessary for a motion to recuse. Because the court mistakenly stated that the necessary vote to recuse an individual under Robert's Rules was a two-thirds vote rather than a majority vote, the court will grant the motion and issue an amended order.

As the Borough correctly indicates, motions for recusal are not included in the list of motions which require a two-thirds vote according to Robert's Rules of Order, Newly Revised (11th ed.). Absent a rule that provides otherwise, the basic requirement for approval of an action by the assembly is a majority vote. RONR (11th ed.), § 44. Under MSB 15.08.075, "the majority vote required shall be four." Therefore, the correct

vote required for recusal is a majority vote, which here, is four votes.

For the foregoing reasons, it is ORDERED that the Matanuska-Susitna Borough Board of Adjustments Limited Motion to Reconsider is GRANTED. The court will issue an amended order with the correct voting requirement.

Dated at Palmer, Alaska, this 8th day of July, 2016.

IN THE SUPERIOR COURT FOR THE STATE OF ALASKA

THIRD JUDICIAL DISTRICT AT PALMER

CENTRAL MONOFILL SERVICES, INC. Appellant, vs. MATANUSKA-SUSITNA BOROUGH BOARD OF ADJUSTMENTS, Appellee.	CASE NO. 3PA-15-01925 CI

AMENDED ORDER

Central Monofill Services ("CMS"), a corporation, appeals the denial of a conditional use permit by the Matanuska-Susitna Board of Adjustment and Appeals ("BOAA"). Because the Commission did not follow the proper procedures governing recusal, the court will reverse the denial of the permit and remand the case for further proceedings.

I. Facts and Proceedings

CMS applied for a conditional use permit for the operation of an inert monofill on two Mat-Su Borough land parcels totaling 118 acres in size. The Matanuska-Susitna Borough Planning Commission held a public hearing on the permit on December 1, 2014. In response to an inquiry from the Commission Chairman as to whether any of the Commissioners in attendance had any potential conflicts of interest, Commissioner Kendig disclosed that his business had sold scrap to Central Environmental, Inc.

("CEI"), a corporation owned by the same individuals as the ones who own CMS. Kendig stated that the most recent sale occurred in late summer or early fall of 2014, but prior to that transaction, he had not done business with CEI in "four or five years." Appellant's Excerpt of Record, p. 168. He further stated that he was "confident in saying that I can be impartial" with respect to CMS's application, and that he did not view occasional sales to CEI to constitute a conflict of interest. Id., p. 172.

The Deputy Borough Attorney informed the Commissioners that Kendig's sale of scrap to CEI raised the question of whether he should recuse himself under MSB 2.71.080, which provides that an official must recuse himself from acting in any proceeding "that involves any person who is, or has been, a client of the official or the official's firm or partnership within the 12-month period immediately preceding the date of the action." The Borough Clerk advised the Commission in this respect that "it's up to the Commission to determine whether or not [Kendig] can stay," thereby framing the issue before the Commission as requiring the Commission to determine whether to allow Kendig to participate in the permit application hearing and voting. Counsel for CMS and the Deputy Borough Attorney informed the Commission that the vote should address whether Kendig should be required to recuse himself, as opposed to whether he could stay.

The Commission decided to follow the Clerk's advice. It also concluded that Kendig should not be allowed to vote on the question of whether he would be allowed to participate. The Chair accordingly called for and received a motion "to allow Mr. Kendig to remain in the discussion [of] Resolution 14-33." Four affirmative votes are required to pass a motion. MSB 15.08.075 ("All board actions shall be by vote of a majority of the board's authorized membership; the majority vote required shall be four."); Appellant's Excerpt of Record, pp. 197, 200. When the motion in question was heard, there were five commissioners of seven in attendance. One of those present was Kendig, who was not allowed to participate. Of the four participants deemed eligible to vote, three voted to allow Kendig to participate and one voted against Kendig's participation.[1] Kendig therefore was precluded from participating in discussing and voting on CMS's permit application.

The Commission then proceeded with the December 1, 2014 public hearing regarding CMS's application, but was unable to complete the hearing on that date. It held a second hearing on December 15, 2014. At the beginning of the December 15th hearing, counsel for CMS re-raised the issue that the motion regarding Kendig's participation had been improperly framed and that recusal was not required under MSB 2.71.080. Counsel also

[1] Commissioner Endle dissented.

called attention to an email from the Borough Clerk to the Commission in which she had stated that the vote should instead have been properly framed as "does Mr. Kendig have a conflict of interest." The Chair declined to revisit the issue.

At the conclusion of the December 15, 2014 hearing, the Commission voted on whether to pass the resolution to approve CMS's conditional use permit. The vote was three in favor and three against[2], which meant that the permit application was denied after it did not receive the four favorable votes required to pass.

After the vote, the Deputy Borough Attorney advised the Commission that it was required to issue written findings and conclusions, and that because the application was denied based on a 3-3 vote, both those in favor and those against should submit proposed findings and conclusions. At a January 5, 2015 hearing, the Commission voted to adopt and approve the findings of fact and conclusions of law to support the Commission's denial of CMS's application, with four votes in favor and two opposed.[3] The Commission did not present for adoption any findings of fact and conclusions of law in support of the vote to approve CMS's application.

---

[2] Commissioners Kapperich, Raucehnstein and Walden voted in favor of the resolution, and Commissioners Endle, Adams, and Healy voted against it.
[3] Commissioner Walden voted to approve the findings and conclusions supporting the denial of the conditional use permit, even though he had voted to approve the permit.

CMS timely appealed to the Board of Adjustment and Appeals ("BOAA"). On March 31, 2015, BOAA issued its Notice of Right to Appeal and Final Decision, unanimously affirming the Commission's denial of CMS's application. CMS timely filed this appeal on April 30, 2015.

II. Standard of Review

AS 22.10.020(d) provides this court with jurisdiction over appeals from administrative agency decisions. The court applies the "substitution of judgment standard to questions of law where no agency expertise is involved," Davis Wright Tremaine LLP v. State, Dep't of Admin., 324 P.3d 293, 299 (Alaska 2014), or "where the agency's specialized knowledge and experience would not be particularly probative as to the meaning of the statute." Tesoro Alaska Petroleum Co. v. Kenai Pipe Line Co., 746 P.2d 896, 903 (Alaska 1987). Under the substitution of judgment standard, the court may "substitute [its] own judgment for that of the agency even if the agency's decision had a reasonable basis in law." Id. (internal citations omitted). Courts also "review an agency's application of its own regulations for whether the agency's decision was 'arbitrary, unreasonable, or an abuse of discretion,'" which "requires [courts] to give deference to an administrative determination 'if it has a reasonable basis in law and fact.'" Alaska Cmty. Action on Toxics

v. Hartig, 321 P.3d 360, 366 (Alaska 2014)(internal citations omitted).

The initial issue to be resolved in this appeal is whether the Commission properly followed its own procedures for recusal of a board member. This is a question of law to which no deference is required. The Borough's decision to deny the permit is subject to the more deferential standard of review.

III. Analysis

A. *The Motion Presented to the Commission on Commissioner Kendig's Recusal Was Improperly Framed*

A key issued raised by CMS is that the Commission improperly framed the motion before it when it voted on Kendig's recusal. According to CMS, the proper motion would have been a motion to disallow Kendig's participation in the hearing, as opposed to whether Kendig should be allowed to participate in the hearing. CMS further claims that the Commission should have presumed as true Kendig's own conclusion that he could be fair and impartial when voting on CMS's permit application, unless they decided that, based on the evidence in the record, a vote on recusal was necessary. And CMS argues that Kendig should have been allowed to vote on his recusal because Robert's Rules of Order ("Robert's Rules") specifically allows a member to vote on questions affecting himself, including whether that member should be recused.

The Borough responds that the court should refrain from addressing whether the Commission properly followed its own parliamentary procedures preceding Kendig's recusal because "parliamentary rules are merely procedural and not substantive" and "[h]ence, they may be waived or disregarded by the legislative body." Appellee's Brief, pp. 41-42 (citing 59 Am. Jur. 2d Parliamentary Law § 5). The Borough also relies on Jefferson v. City of Anchorage, 513 P.2d 1099 (Alaska 1973)(finding that the city council could, by its customary practice, waive a procedural requirement) in support of this claim.

Contrary to the Borough's claim, the court has jurisdiction to address the procedures used by the Commission in voting on the recusal issue. Courts typically and properly review decisions of administrative agencies to determine whether the agency followed its own procedures. See, e.g., Copeland v. Ballard, 210 P.3d 1197, 1201 (Alaska 2009); In re Hanson, 532 P.2d 303, 305 (Alaska 1975). The authority cited by the Borough, by contrast, involved procedural decisions by legislative and municipal bodies, not executive branch agencies. In particular, the Am. Jur. treatise cited by the Borough states:

> The courts will not annul an act of a *legislature* or an ordinance of a *municipal council*, merely because one or the other was enacted in disregard of the rules that the legislature or the municipal council...had prescribed for its own government...unless they have proceeded in

> violation of the law of the land, or of the charter of the municipality, which is their organic law.

59 Am. Jur. 2d Parliamentary Law § 5 (emphasis added). And Jefferson, the Alaska Supreme Court was asked to review a procedural action of the Anchorage City Council, again, a legislative body.

The Commission is an executive branch agency and by the Borough's own admission, a quasi-judicial body. The procedural decisions of the Commission may thereby properly be reviewed by the court. (The Court also notes that unlike Jefferson, there is no indication from the record that the Commission voted in this instance (nor was it the Commission's regular practice) to suspend the applicability of Robert's Rules when voting on Kendig's recusal.)

The Commission consists of seven members who are registered to vote on matters before it. MSB 15.08.010. Four votes, which constitutes a majority of the seven members, are required for the Commission to take action. MSB 15.08.075. In the absence of a majority of the number of authorized board seats (defined as a "quorum") present at a meeting, any business transacted is null and void. MSB 4.05.080(B).

When voting on a matter before the Commission, a Commissioner may not take or withhold an official action in order to affect a matter in which the municipal officer has a

substantial financial interest, MSB 2.71.070(A)(2)(d), or "participate in deliberation or vote on question if the commission member...has a substantial financial interest in any property affected by the decision...or could foreseeably profit in any material way through a favorable or unfavorable decision." MSB 15.08.150(A). If the specific conflict of interest involves a person who has been a "client" of one of the officials in the past year, MSB 2.71.080(a) requires that that official recuse himself:

> "A municipal officer shall recuse himself from acting on any matter or proceeding coming before a borough-elected body, board, commission, or committee of which the official is a member when the matter or proceeding involves any person who is, or has been, a client of the official or the official's firm or partnership within the 12-month period immediately preceding the date of the action."

MSB 4.05.080(A) provides that "[a]ll meetings shall be conducted in accordance with the current edition of Robert's Rules of Order, Newly Revised." See also MSB 15.080100 ("Meetings shall be conducted under the current edition of Robert's Rule of Order Newly Revised, and such modified or amended rules as may be adopted by the commission."). As to whether a commissioner may vote on matters that involve potential conflicts of interest, Robert's Rules states: "It is a general rule that no one can vote on a question in which he has a direct personal or pecuniary interest." RONR (11th ed.), Ch. 46. However, Robert's Rules provides limited exceptions to this

rule, such as matters that affect more than one person at a time, like salary increases of board members. Id. It is in the context of these limited exceptions that Robert's Rules states: "If a member could in no case vote on a question affecting himself, it would be impossible...for a legislature to vote salaries to members, or for the majority to prevent a small minority from preferring charges against them and suspending or expelling them." Id. Finally, Robert's Rules reiterates: "A sense of delicacy usually prevents a member from exercising this right of voting in matters affecting himself except where his vote might affect the result." Id.

The plain language of MSB 2.71.080 requires the Commission to determine whether a Commissioner should be recused from participating in a proceeding. This requires an affirmative vote on recusal by the Commission, not an indirect vote on whether the Commissioner may remain. In other words, the issue properly framed for the Commission's vote was whether Kendig should be recused. Instead, as stated earlier, the Commission improperly framed the issue as whether to allow Kendig to participate in deliberations, which thereby allowed one vote to prevent Kendig's participation in the hearing on CMS's permit application, rather than the majority vote required by Robert's Rule's. RONR (11th ed.), Ch. 48.

The Commission did, however, properly decide that Kendig could not vote on his own recusal. Kendig clearly has a direct personal interest in his recusal, for as an active, appointed commissioner, Kendig certainly has a personal interest in his own involvement via continued participation and deliberation on matters before the Commission. Nor is the issue one that, despite Kendig's own personal or pecuniary interest, affects more than just him. Kendig therefore should not vote on the issue of his recusal. Cf. AS 22.20.020(c)(another judge must review a judge's decision to deny recusal).

B. Relief

CMS requests that the court simply order the Commission to hold a vote on the recusal issue, and if Kendig is allowed to participate, to have him vote based on the record developed at the December 2014 hearings. The Borough contends that if the court decides that the Commission failed to follow the correct procedure on remand, then the overall decision must be vacated and a new hearing held.

The court agrees with the Borough. The Commission voted 3-3 on the permit application, which means that the Commission's procedurally incorrect decision on Kendig's recusal had a significant effect on the outcome. This requires the permit decision to be vacated altogether, which in turn entails that all of the other challenges raised by CMS to the permit denial

are moot and need not be addressed by this court. The court notes in this respect that the CMS permit was very controversial - if CMS' proposed procedure were to be followed, then if Kendig were allowed to participate, he may well vote to grant the permit, which would raise serious and substantial legal issues regarding whether anyone opposed to the permit would have an opportunity to challenge that decision either before the BOAA or in court.

The court accordingly will remand this case to the Commission with an order that it revisit the recusal issue in a manner consistent with this order and then revisit CMS's permit application. The Commission should prepare findings of fact and conclusions of law as to any recusal decision it may make, as well as on the merits of CMS' permit application.

IV. Conclusion

For the foregoing reasons, it is ORDERED that the Borough's decision to deny CMS's permit is REVERSED and this case is remanded to the Commission for further proceedings consistent with this order.

Dated at Palmer, Alaska this 8th day of July, 2016.

MATANUSKA-SUSITNA BOROUGH
PLANNING COMMISSION RESOLUTION NO. 15-01(AM)

A RESOLUTION OF THE MATANUSKA-SUSITNA BOROUGH PLANNING COMMISSION ADOPTING FINDINGS OF FACT AND CONCLUSIONS OF LAW TO SUPPORT THEIR FAILURE TO APPROVE PLANNING COMMISSION RESOLUTION 14-33.

WHEREAS, Planning Commission Resolution 14-33 recommended approval of a conditional use permit, subject to conditions, for the operation of an inert material monofill on parcels 17N02E18C010 and 17N02E19B006, within Township 17 North, Range 2 East, Sections 18 and 19, Seward Meridian; and

WHEREAS, on December 1st and 15th, 2014, the Planning Commission held a public hearing on Resolution 14-33; and

WHEREAS, the Planning Commission's vote on the motion failed to garner a majority vote on December 15, 2014 which constitutes denial of the conditional use permit; and

WHEREAS, comments received regarding the proposed monofill raised the following concerns:

- Material has been dumped without MSB or ADEC permits
- Hazardous waste could end up in the landfill
- Trash was dumped in the water
- Water pollution
- Health problems
- Pollution of surrounding lakes
- Protection of watershed and aquifer
- Windblown unhealthy dust and particulates from the monofill, including asbestos
- Contamination of water wells

- Windblown materials/debris onto surrounding properties
- Previous problems with gravel extraction on this property and rising water table
- Breach of berm between two of the manmade lakes and impact on surrounding water levels
- Lack of oversight and planning
- Applicant's disregard for regulations
- Lack of CMS's ability to manage and provide oversight of the facility
- Failure to reclaim the property
- Contamination of soil
- Lowering of property values
- Visual impacts to the Glenn Highway, a Scenic Byway
- Threat to migratory and breeding birds
- How the redesign of the Glenn Highway will affect this site
- Rising water levels of nearby lakes
- Improper handling and disposal of asbestos
- Depositing of lead based paint, mercury and heavy metals in the monofill
- Close proximity to residential area
- Contamination of fish in Canoe, Kepler-Bradley Lake system
- Inconsistent with comprehensive plans
- Highway safety and access issues; and

WHEREAS, Goal LU-1 of the Borough-Wide Comprehensive Plan (2005 Update) is to *Protect and enhance the public safety, health, and welfare of Borough residents*; and

WHEREAS, Policy LU1-1 Borough-Wide Comprehensive Plan (2005 Update)is to *Provide for consistent, compatible, effective, and efficient development within the Borough*; and

WHEREAS, Goal LU-2 of the Borough-Wide Comprehensive Plan (2005 Update) is to *Protect residential neighborhoods and associated property values*; and

WHEREAS, Policy LU2-1 of the Borough-Wide Comprehensive Plan (2005 Update) is to *Develop and implement regulations that protect residential development by separating incompatible uses, while encouraging uses that support such residential uses including office, commercial and other mixed-use developments that are shown to have positive cumulative impacts to the neighborhood*; and

WHEREAS, Goal LU-3 of the Borough-Wide Comprehensive Plan (2005 Update) is to *Encourage commercial and industrial development that is compatible with residential development and local community desires*; and

WHEREAS, Policy LU3-1 of the Borough-Wide Comprehensive Plan (2005 Update) is to *Develop and implement regulations that provide for non-residential development; and*

WHEREAS, Goal LU-4 of the Borough-Wide Comprehensive Plan (2005 Update) is to *Protect and enhance the Borough's natural resources including watersheds, groundwater supplies and air quality; and*

WHEREAS, Policy LU4-1 of the Borough-Wide Comprehensive Plan (2005 Update) is to *Identify, monitor, protect, and enhance the quantity and quality of the Borough's watersheds, groundwater aquifers, and clean air resources; and*

WHEREAS, Goal CQ-1 of the Borough-Wide Comprehensive Plan (2005 Update) is to *Protect natural systems and features from*

the potentially negative impacts of human activities, but not limited to, land development; and

WHEREAS, Policy CQ1-2 of the Borough-Wide Comprehensive Plan (2005 Update) is to *Manage activities affecting air, vegetation, water, and the land to maintain or improve environmental quality, to preserve fish and wildlife habitat, to prevent degradation or loss of natural features and functions, and to minimize risks to life and property; and*

WHEREAS, this site is located within the boundary of the Core Area Comprehensive Plan (2007 Update) boundary; and

WHEREAS, Policy 1-B of the Land Use Goal within the Core Area Comprehensive Plan (2007 Update) is to *Promote an orderly land use pattern suited to the demand for attractive settings in which to live, work, shop, learn, play, and carry on other daily activities;* and

WHEREAS, Policy Discussion related to policy 1-B within the Core Area Comprehensive Plan (2007 Update) states *As the Core Area's population grows – it is forecast to double by 2025 and absorb most of the remaining vacant land in the Core Area – the limited vacant land supply must provide a balanced supply of well-located sites for homes, businesses, private and public institutions, industry, parks and recreation, public improvements, and other purposes. The plan needs to provide a place for every permitted land use, but not all land uses go*

well side-by-side. Some uses such as residences and open space or retail trade and service business are usually compatible and enhance each other. Others, like heavy industrial activities and residential subdivisions, make poor neighbors and are best separated by distance or buffers; and

WHEREAS, Goal 7 of the Core Area Comprehensive Plan (2007 Update) is to *Protect and conserve the natural resources that support the well-being of residents and the region's tourism and recreation economy;* and

WHEREAS, Policy 7-A of the Core Area Comprehensive Plan (2007 Update) is to *Protect groundwater supplies and quality*; and

WHEREAS, Policy Discussion related to policy 7-A of the Core Area Comprehensive Plan (2007 Update) states *Many existing and future residences and businesses will depend on on-site groundwater resources for their water supply. Protection of the supply and quality of groundwater is vital to sustain this arrangement*; and

WHEREAS, Policy 7-B of the Core Area Comprehensive Plan (2007 Update) is to *Protect surface water quality*; and

WHEREAS, Policy Discussion related to policy 7-B of the Core Area Comprehensive Plan (2007 Update) states *The Core Area's many lakes are valuable natural and economic assets. They provide an attractive setting for residential development,*

enhance property values, support a variety of public and private recreational activities, and provide natural habitat, absorb runoff. These lakes are linked to streams and wetlands with similar positive values. The borough's existing program of lake management plans already provides some protection for surface water quality; and

WHEREAS, the Alaska Department of Environmental Conservation has not approved a permit for this development, as proposed; and

WHEREAS, the previous use of this site was for earth materials extraction. There are pre-existing legal nonconforming use rights for earth materials extraction for this property, which means that the industrial use was not approved under the current regulatory structure or evaluated for compatibility with surrounding land uses; and

WHEREAS, The proposed monofill is an industrial use and is an incompatible use with the surrounding residential areas as there is the possibility of contamination of drinking water wells and surrounding lakes within the area; and

WHEREAS, the underlying water table level is subject to significant fluctuations resulting from adjacent land use activities including the spill way located on the property and the dredging operation immediately to the north; and

WHEREAS, the Middle Pond on the site is unable to reach its predevelopment equilibrium when surface water is diverted out of the Middle Pond, as is currently occurring through the spillway; as testified by Charlie Cobb, State Dam Safety Engineer for the Water Resources Section of the Department of Natural Resources; and

WHEREAS, water levels in the three gravel pit ponds on site tend to sit at three different elevations and are acutely related to surface connections, but also related to groundwater levels in the vicinity or vice versa; as testified by Charlie Cobb, Dam Safety Engineer; and

WHEREAS, the embankments between the three surface ponds of the gravel pits, and possibly the surrounding shoreline, may not be dynamically stable due to the liquefaction potential of silt and sand soils in the vicinity; as testified by Charlie Cobb, Dam Safety Engineer; and

WHEREAS, as conveyed by the Department of Natural Resources Water Resources Section, the continued diversion of surface water and the integrity of the dam at the site are unresolved; and

WHEREAS, the applicant has not addressed how they will monitor or manage the seasonal high water table fluctuations to ensure that the bottom of the monofill is not annually saturated by groundwater; and

WHEREAS, a hydrologic report submitted to the Borough early in 2014 predicts a potential 2-foot water table rise resulting from dredging operations adjacent to the proposed monofill site to the north; and

WHEREAS, contaminants from the monofill will likely travel to surrounding drinking water wells and lakes; and

WHEREAS, a hydrology report within the record conveys that there is a high risk of water table contamination due to leachate; and

WHEREAS, the CMS hydrologists (Maddox & Associates) used annual precipitation and evaporation rates, which ignores the fact that precipitation at the site is not evenly spread throughout the year; and

WHEREAS, JA Munter Consulting Inc. cited a recent USGS study which characterizes the site as transitional between maritime and continental climates and the USGS estimates that 1.4 inches of water per year will recharge groundwater at this site, which equates to more than one million gallons of water, which is a significant volume of water to percolate through the waste material and enter the groundwater system; and

WHEREAS, as proposed, the monofill will be unlined with no system to capture, treat, or monitor polluting leachate which is likely to leave the site; and

WHEREAS, soils in the area of the monofill site are very

porous loose gravels and glacial loess, and offer little or no filtering capacity for fluids being emitted or drained from the fill. Without a liner, a ten foot separation is not sufficient to prevent leachate from reaching the water table, thus increasing the risk of contamination of the water resources in the area; and

WHEREAS, the monofill is designed to have water flow through the construction debris with an average hydro conductivity of approximately 2.0 x 10-2 cm/second, as determined by an engineering report submitted by the applicant; and

WHEREAS, contaminants typically found in groundwater surrounding construction and demolition landfills include cadmium, lead, iron, manganese, several chlorinated volatile organic compounds, sulfate, hydrogen sulfide, and TDS (Total Dissolved Solids). In addition, chromium and arsenic are found if chrominated copper arsenate-treated wood is disposed in the landfill; and

WHEREAS, there is the potential for the construction and demolition monofill to undergo spontaneous combustion or to catch fire by other outside sources. In the event that the material catches fire, a common method for fire suppression is application of copious amounts of water and foam, which could

leach into the water table and cause dramatic and sudden increase of polluting leachate; and

WHEREAS, the applicant did not propose a water quality monitoring program as part of the application; and

WHEREAS, the applicant has not provided a plan for remediation should the water table be polluted beyond safe drinking water levels; and

WHEREAS, as proposed, it is not possible to set conditions to adequately protect the groundwater and aquifer from anticipated negative effects of the monofill; and

NOW, THEREFORE, BE IT RESOLVED, that the Matanuska-Susitna Borough Planning Commission hereby adopts the aforementioned findings of fact and makes the following conclusions of law supporting denial of Planning Commission Resolution 14-33:

1) the commission cannot find that this conditional use permit will preserve or not detract from the value, character, and integrity of the surrounding area as required by 17.60.100(B)(1); and

2) the commission concludes that it cannot find that this conditional use permit will not be harmful to the public health, safety, convenience, and welfare as required by 17.60.100(B)(2);and

3) the proposed monofill is inconsistent with the goals and policies of the Borough-Wide Comprehensive Plan (2005 Update) and the Core Area Comprehensive Plan (2007 Update) because the monofill is an industrial use that is incompatible with the neighboring residential areas.

BE IT FURTHER RESOLVED that this is a final determination which may be appealed in accordance with MSB 15.39.140 by filing a written notice of appeal with the Borough Clerk within 21 days from the date this determination was issued. If an appeal is not filed as described in the preceding sentence, the right to appeal is forfeited.

ADOPTED by the Matanuska-Susitna Borough Planning Commission this 5th day of January, 2015.

JOHN KLAPPERICH, Chair

Appellant	)	
	)	

NOTICE OF RIGHT TO APPEAL AND FINAL DECISION

NOTICE IS HEREBY GIVEN, that the Matanuska-Susitna Borough Board of Adjustment and Appeals (BOAA), on March 31, 2015, rendered the following final decision regarding the appeal filed in the above referenced matter. This final decision may be appealed within 30 days of the date of this decision, pursuant to MSB 15.39.250 and the Alaska Rules of Appellate Procedure, Part 600.

FINDINGS OF FACT

1. This appeal was filed in a timely manner.
2. The BOAA has jurisdiction over this administrative appeal from the decision of the Planning Commission on the conditional use permit application for a construction and demolition monofill pursuant to MSB 15.39.030(A)(2).
3. The Planning Commission's decision in this matter embodied in their Resolution Serial No. 15-01(AM) includes numerous

findings of fact supported by substantial evidence contained in the administrative record as follows:

a. The proposed monofill is inconsistent with numerous provisions of Borough comprehensive plans. R. 909, 947, 1040, 1124, 1519, 2103, 2804, 2852, 3014-3015.

b. Previous use of this site was for earth materials extraction, which had pre-existing legal nonconforming use rights for earth materials extraction, which means that the former industrial use of the property was not approved under the current regulatory structure or evaluated for compatibility with surrounding land uses. R. 15, 2833, 3036;

c. The applicant has not addressed how they will monitor or manage the seasonal high water table fluctuations to ensure that the bottom of the monofill is not annually saturated by groundwater. R.11-12;

d. A hydrologic report submitted to the Borough early in 2014 predicts a potential 2-foot water table rise resulting from dredging operations adjacent to the proposed monofill site to the north. R. 26, 901, 939, 1165, 1167, 1633, 2774-2775; See also Supplemental Record 1-41 "Groundwater Modeling Report, Alaska Sand and Gravel Palmer Pit".

e. The Central Monofill Services hydrologists (Maddox and Associates) used annual precipitation and evaporation rates, which ignore the fact that precipitation at the site is not evenly spread throughout the year. R. 1571;

f. The proposed monofill would be unlined with no system to capture, treat, or monitor leachate. R. 4, 11-12;

g. Soils in the area of the monofill site are very porous loose gravels and glacial loess, and with marginal filtering capacity for fluids being emitted or drained from the fill. R. 901, 958, 1082, 1145, 1289, 1899, 2321, 2829, 2941;

h. The monofill is designed to have water flow through the construction debris with an average hydro conductivity of approximately 2.0×10^{-2} centimeters per second, as determined by an engineering report submitted by the applicant. R. 410;

i. There is the potential for the construction and demolition monofill to catch fire. In the event that the material catches fire, a common method for fire suppression is application of copious amounts of water and foam, which could leach into the water table and cause dramatic and sudden increase of polluting

leachate. R. 1307, 2468-2469, 2470-2476, 2477-2499, 2500-2504, 2506-2509, 2510-2521, 2838-2839, 2849, 2946-2949, 2972-2973, 2983, 2995-2996;

j. The applicant did not propose a water quality monitoring program as part of the application. R. 11-12, 2648;

k. The applicant has not provided a plan for remediation should the water table be polluted beyond safe drinking water levels. R. 3-33.

CONCLUSIONS OF LAW

Based upon the above findings, the Board of Adjustment and Appeals makes the following conclusions:

1. The appeal was filed in a timely manner.
2. The BOAA has jurisdiction over the appeal of the decision of the Planning Commission denying the conditional use permit for the proposed construction and demolition monofill pursuant to MSB 15.39.030(A)(2).
3. The decision contained in Planning Commission Resolution Serial No. 15-01 contained numerous findings of fact supported by substantial evidence contained in the record.

4. The BOAA defers to the Planning Commission's findings of fact as required by MSB 15.39.210(B) because the findings of fact are supported by substantial evidence contained in the record that support the legal conclusions so that the Planning Commission could not find: (1) that the proposed construction and demolition monofill would preserve and not detract from the value, character, and integrity of the surrounding area; and (2) that the proposed construction and demolition monofill would not be harmful to the public health, safety, convenience and welfare, MSB 17.60.100 (B)(1)and(2) General Standards.

5. The BOAA lacks jurisdiction to adjudicate Appellant's constitutional fair hearing/due process claims of an alleged conflict by Planning Commissioner Thomas Healy and an alleged lack of a conflict by Planning Commissioner William Kendig. MSB 15.39.030(A)(2); *Alaska Public Interest Research Group v. State*, 167 P.3d 27, 36 (Alaska 2007) (*citing* Dougan v. Aurora Elec. Inc., 50 P.3d 789, 795 n. 27 (Alaska 2007)); 8A McQuillin Mun. Corp. § 25:257 (3d Ed. 2012).

6. Assuming that the BOAA had jurisdiction over the Appellant's constitutional fair hearing due process

claims, the Appellant waived this claim by failing to raise it until three weeks after the Planning Commission voted to deny the conditional use permit. See Griswold v. Homer City Council, 310 P.3d 938, 942 (Alaska 2013).

7. The BOAA does not have jurisdiction over the Appellant's constitutional fair hearing due process claims regarding William Kendig.

8. The BOAA does not have jurisdiction over the Appellant's constitutional fair hearing due process claims regarding Thomas Healy.

FINAL DECISION

Based upon the above Findings of Fact and Conclusions of Law, the Matanuska-Susitna Borough Board of Adjustment and Appeals affirms the Planning Commission's denial of the conditional use permit in the captioned case.

Dated this 31 day of March, 2015.

Advisory Opinion No. 16-01

October 10, 2016

On September 1, 2016, the Board of Ethics received a Request for an Advisory Opinion from Mr. Bill Kendig, who is a member of the Planning Commission. The Board of Ethics met in a special meeting at 10 a.m. on October 10, 2016, to consider the request of Mr. Kendig.

Specific Question for the Board of Ethics

Mr. Kendig has requested an Advisory Opinion from the Board on the following question:

Should Mr. Kendig recuse himself from discussion and voting on Planning Commission Resolution Serial No. 14-33, which has been remanded back to the Planning Commission by the Superior Court.

Findings

The Board of Ethics finds that in his most recent request, Mr. Kendig states that he has not done business with Central Monofill Services (CMS), but with Central Environmental, Inc. (CEI), which are two separate companies.

The Board of Ethics finds that consistent with the amended order in 3PA-15-01925 CI, that Mr. Kendig stated "that he had done business with CEI, which is a corporation owned by the same individuals as the ones who own CMS." Mr. Kendig stated "that the most recent sale occurred in the late summer or early fall of 2014, but prior to that transaction, he had not done business with CEI in four or five years." Appellant's Excerpt of Record, p. 168.

The Board of Ethics finds that Per MSB 2.71.080 Mr. Kendig was previously recused from voting on Planning Commission Resolution No. 14-33 regarding a conditional use permit (CUP) as he had done business within the last 12-month period with a corporation that was directly related to CMS, which is the company that applied for the CUP.

The Board of Ethics finds that Planning Commission Resolution No. 14-33 denied a conditional use permit for a monofill (private landfill) for CMS. The resolution failed with three Planning Commissioners voting in support and three voting opposed. Mr. Kendig was recused due to his prior business relations.

The Board of Ethics finds that in their Advisory Opinion No. 15-01, Conclusion No. 5, that "The Board of Ethics concludes that MSB 2.71.080, Recusal did apply in relation to Planning Commission Resolution No. 14-33, but that Mr. Kendig was properly recused and that resolution is not at issue for this request."

The Board of Ethics finds that Planning Commission Resolution 14-33 is currently at issue for Board of Ethics Advisory Opinion No. 16-01.

Conclusions

1. The Board of Ethics concludes that Mr. Kendig is eligible to sit on the Planning Commission under MSB 4.05.030.

2. The Board of Ethics concludes that Mr. Kendig is subject to the Borough code, under MSB 4.05.030.

3. The Board of Ethics concludes that the code of ethics applies to Mr. Kendig as a municipal official under MSB 2.71.030.

4. The Board of Ethics concludes that as a Planning Commission Member Mr. Kendig does have the ability to take official action as he does vote in support or opposition of Planning Commission resolutions that are quasi-judicial in nature, such as whether to approve a CUP, which is the subject of Resolution No. 14-33.

5. The Board of Ethics concludes that MSB 2.71.080, Recusal, does apply in relation to Planning Commission Resolution No. 14-33, as they previously stated in Board of Ethics Advisory Opinion 15-01.

Summary of Opinion

The Board of Ethics has determined that Mr. Kendig does have a conflict under MSB 2.71.070, Conflict of Interest; Prohibited Acts, as it relates to Planning Commission Resolution No. 14-33 and should recuse himself under MSB 2.71.080, from discussion or voting on the question of a conditional use permit for CMS.

Advisory Opinion No. 15-01

August 27, 2015

On July 14, 2015, the Board of Ethics received a Request for an Advisory Opinion from Mr. Bill Kendig, who is a member of the Planning Commission. The Board of Ethics met in a special meeting at 5 p.m. on August 27, 2015, to consider the request of Mr. Kendig.

Specific Question for the Board of Ethics

Mr. Kendig has requested an Advisory Opinion from the Board on the following question:

Should Mr. Kendig recuse himself from discussion and voting on Planning Commission Resolution Serial No. 15-26?

Findings

The Board of Ethics finds that Per MSB 2.71.080 Mr. Kendig was recused from voting on Planning Commission Resolution No. 14-33 regarding a conditional use permit (CUP) as he had done business within the last 12-month period with a corporation that was related to Central Monofill Services (CMS), which is the company that applied for the CUP.

The Board of Ethics finds that Planning Commission Resolution No. 14-33 denied a conditional use permit for a monofill (private landfill) for CMS. The resolution failed with three Planning Commissioners voting in support and three voting opposed. Mr. Kendig was recused due to his prior business relations.

The Board of Ethics finds that CMS appealed the denial of the CUP to the Board of Adjustment and Appeals (BOAA); the BOAA unanimously affirmed the Planning Commissions' denial of the CUP.

The Board of Ethics finds that CMS appealed the BOAA decision to the Superior Court, which is current and ongoing.

The Board of Ethics finds that the Planning Commission currently has Planning Commission Resolution No. 15-26 before them, which would recommend that the Assembly adopt legislation that would prohibit private landfills within the core area.

The Board of Ethics finds that in his request, Mr. Kendig states "that it could be argued that [Planning Commission Resolution No.] 15-26 would affect the applicants [CMS] if they were to win there [sic] appeal."

The Board of Ethics finds that Mr. Kendig would like an advisory opinion on whether he should recuse himself from Planning Commission Resolution No. 15-26.

Conclusions

1. The Board of Ethics concludes that Mr. Kendig is eligible to sit on the Planning Commission under MSB 4.10.030.

2. The Board of Ethics concludes that Mr. Kendig is subject to the Borough code, under MSB 4.10.030.

3. The Board of Ethics concludes that the code of ethics applies to Mr. Kendig as a municipal official under MSB 2.71.030.

4. The Board of Ethics concludes that as a Planning Commission Member Mr. Kendig does have the ability to take official action as he does vote in support or opposition of Planning Commission resolutions; however, the official action is advisory in nature only and does not provide him with a substantial financial interest.

5. The Board of Ethics concludes that MSB 2.71.080, Recusal, did apply in relation to Planning Commission Resolution No. 14-33, but that Mr. Kendig was properly recused and that resolution is **not** at issue for this request.

6. The Board of Ethics concludes that MSB 2.71.070, does not apply in relation to Planning Commission Resolution No. 15-26, because only the Borough's legislative body, which is the Borough Assembly, may take official legislative action that could potentially impact an appeal at the Superior Court level.

Summary of Opinion

The Board of Ethics has determined that Mr. Kendig does not have a conflict under MSB 2.71.070, Conflict of Interest; Prohibited Acts, as it relates to Planning Commission Resolution No. 15-26.

Existing Conditions and CRS Operating History

Dear Ms. Lee:

Central Monofill Services, (CMS) submits the information below and attached, to provide clarification to recent issues being raised via public comments.

Images are being displayed and distributed that claim to show the current condition of the gravel pit and existence of wetlands. Attached are pictures of the actual existing conditions in the bottom of the Monofill area. Pages 1077 to 1079 of the Dec 1st, 2014 planning commission package includes additional pictures taken by MSB staff in October 2014 of the proposed site. Pages 287 to 297 are the US Corps of Engineers Jurisdictional Determination that no wet Lands exist on this property. Also attached are photos of the ponds that are not part of the monofill. People have claimed these ponds have trash in them. The photos provided show no trash floating around the ponds. MSB and ADEC have investigated claims and visited the site in 2014 and found no trash.

Pictures provided during public comment showing recently raised water levels at surrounding lakes and indicating these are due to activities at our subject property are unfounded. CMS has done no dredging on this property or changes to the property that would increase the flow of water. CMS is working with ADNR on further studies of the region's water. Regional water issues are addressed by AlaskChem Engineers in pages 729 to 760.

Questions have been raised about Central Recycling Services, (CRS) history as an operator based upon an isolated incident in 2013 at the subject property. This incident was resolved to the satisfaction of the agencies in 2013. CRS has successfully operated its Anchorage facility since 2009 and the CMS Salcha Canaday Road Monofill since 2012. Attached is the last ADEC inspection report from August 2014 for the

PH (907) 770-7470 FAX (907) 770-5084
www.centralmonofillalaska.com • cms@centralmonofillalaska.com

CMS facility receiving a score of 100%. Since the fall of 2013 CRS has operated the Birchwood Shooting and Recreation Park, (BSRP) Monofill. This monofill has been in operation for over 20 years along Knik Arm. Eklutna Inc. is the pre-dominate surrounding land owner to this monofill. Pictures of the BSRP Monofill are attached. This is an operational facility with people working and recreating every day on top of and around the Monofill. The BSRP Monofill has been a model of good operation, such that neighbor Eklutna Inc. is working with CRS to develop another Monofill within the Municipality of Anchorage. Within the previously submitted documents are several letters of support from our neighbors of our existing facilities.

Concerns raised over the proximity of the monofill to natural water bodies can be compared to existing CRS operations. The Salcha Canaday Monofill site contains wet lands and is adjacent to Little Salcha Creek. The CRS Anchorage recycle facility is on the banks of Ship Creek. The BSRP Monofill is on the bank of Knik Arm as show in the attached photos. These sites among many others around Alaska have operated near sensitive bodies of water without incident.

Should you have any further questions or require further clarification please do not hesitate to ask.

Respectfully,

Shane Durand

Re: September 09, 2014 Inspection of Salcha Canaday Road C & D Monofill, Permit #SWZA063-17

Dear Mr. Jacques:

The Alaska Department of Environmental Conservation Solid Waste Program (ADEC) completed its first annual inspection of the Salcha Canaday Road C & D Monofill on September 09, 2014. I would like to thank Sean Holland for assisting me with the inspection.

The facility is being managed and operated excellently and received a compliance score of 100% during this year's inspection. Great Job! Specific details of the inspection are provided in the enclosed inspection checklist.

The Regulated Asbestos Containing Material (RACM) cell was nearly completed at the time of the inspection and has likely been completed. However, since the cell was not completed at the time of the inspection and RACM was not being received, the questions in the inspection checklist pertaining to RACM were not scored since they were not applicable at the time. During next year's inspection, these sections will be applicable.

Thank you for running a great operation. If you have any questions about this letter or the enclosed inspection checklist, please contact me by telephone at 907-451-2134 or by email at neil.lehner@alaska.gov.

Sincerely,

Neil Lehner
Environmental Program Specialist
Solid Waste Program

Inert Waste Monofill Inspection Checklist

Alaska Department of Environmental Conservation
Division of Environmental Health
Solid Waste Program

Part One: ADEC Information Gathering

This section should be filled out completely, prior to the site visit. This section is not scored, but the information will be used during the site visit to determine compliance with requirements.

#	Part One: ADEC Information Gathering
1	**PERMIT AND OPERATING PLAN** – Review permit and operating plan to familiarize yourself with the requirements and approved operations for this landfill. Does the facility have a current ADEC permit? [X] Yes [ ] No Permit Number: SWZA063-17 Expiration Date: 6/17/2017
2	**SITE/DEVELOPMENT PLANS** – Review site plans and development plans to familiarize yourself with the approved layout of the landfill and the conditions at the site. Check the conditions that exist at the landfill: [X] Is the landfill located in or near wetlands? [X] Is the landfill located on permafrost? (It is in a general area of discontinuous permafrost) [ ] Is the landfill located in a 100-year floodplain? [ ] Are there any drinking water wells within 500 feet of the landfill property boundary? Has a current/up-to-date site map been submitted? Yes
3	**PREVIOUS INSPECTIONS** – Review previous inspection forms. List any issues that may still be outstanding that should be investigated. This is the first inspection.
4	**COMPLAINTS** – If ADEC has received any complaints regarding the facility, list and describe them below: One complaint was received in June. The individual was concerned with the truck traffic and degradation to the road and also concerned with the number of trucks going to the site. Individual also reported trucks arriving later in the evening.
5	**AUTHORIZED WASTE TYPES** – *The landfill is required to have a permit that authorizes all types of waste disposed at the site.* Check the types of waste that the facility is authorized to dispose: [X] Inert or C&D Waste [X] Regulated Asbestos Containing Material (RACM) *(Must be disposed in separate cell)* [ ] Other
6	**SIGN REQUIREMENTS** – *Many permits require signage that identifies the owner or operator, hours of operation, emergency contacts, or other information.* List any signage requirements specified in the permit:

Inert Waste Monofill Inspection Checklist

Alaska Department of Environmental Conservation
Division of Environmental Health
Solid Waste Program

#	Part One: ADEC Information Gathering
7	**LAND OWNERSHIP** – *The landfill application must contain documentation that the operator is the landowner, or that the operator has obtained authorization from the land owner.* Central Monofill Services is the landowner, Central Recycling Services is now the operator Check the appropriate box. [ ] The operator is the landowner [X] The landowner has authorized the landfill
8	**WAIVERS** – *The landfill may obtain waivers for requirements related to development or operation.* List any ADEC-approved waivers: None
9	**MONITORING REQUIREMENTS** – *A facility may be required to monitor groundwater or surface water. Requirements are specified in the permit or approved monitoring plan. By regulation, monitoring reports must be submitted to ADEC for groundwater and surface water. This information will help you determine if the operating record is complete.* Check the types of monitoring that the facility is required to conduct, note the required sampling frequency, and check if reports must be submitted to DEC:
10	**MONITORING LOCATIONS** – *Sampling must be conducted at approved wells or sites. Locations are specified in the monitoring plan.* Make a copy of a site plan or map that shows the locations of monitoring wells, surface water sampling sites, or other approved monitoring locations. Take the map with you to assist in field inspection.
11	**ADDITIONAL PERMIT REQUIREMENTS** List any additional permit requirements that are not addressed in the inspection checklist. 1. Notify ADEC when large quantities of RACM are accepted 2. Submit updated site development plans by Dec. 31 each year 3. Notify ADEC before the amount of waste deposited exceeds the annual expected average

✓	Type	Sampling frequency	Report to DEC required?
	Groundwater		
	Surface Water		

Part Two: ADEC Records Review

This section should be completed and scored in the office, prior to conducting the site visit.

Inert Waste Monofill Inspection Checklist

Alaska Department of Environmental Conservation
Division of Environmental Health
Solid Waste Program

#	Part Two: ADEC Records Review	POINTS Possible	POINTS Score
1	**FEES** – *The landfill is required to pay annual and other fees to ADEC.* 18 AAC 60.700 Is the facility current on payment of all fees? [X] Yes [ ] No Date of last payment: 12/26/13 OR Amount owed:	5	5
2	**MONITORING REPORTS** – *A facility may be required to monitor groundwater or surface water. Groundwater and surface water reports MUST be submitted to ADEC.* ***NOTE to inspector:*** *The project manager should be reviewing and communicating about monitoring reports as they are received.* 18 AAC 60.810, 18 AAC 60.830, permit condition Is Monitoring required? If so, does the facility submit the required monitoring reports to ADEC? Do monitoring reports address all required types of monitoring? Are monitoring reports complete and contain required analyses?	NA	NA
3	**FINANCIAL ASSURANCE** –*The landfill may need to demonstrate financial assurance to cover closure and post closure costs if monitoring is being done. The local government financial test is the most commonly used mechanism. Some financial assurance mechanisms require an annual update.* 18 AAC 60.235, 18 AAC 60.265 Check the type of financial assurance used : [ ] Local government financial test (requires annual update) [ ] Corporate financial test (requires annual update) [ ] Trust Fund [ ] Surety Bond guaranteeing payment or performance [ ] Letter of credit [ ] Insurance [ ] Corporate guarantee [ ] Local government guarantee [ ] Other state-approved mechanism What is the date of the latest financial assurance documentation?	NA	NA

Part Three: Landfill Records

This section should be completed at the landfill facility during the site visit.

Inert Waste Monofill Inspection Checklist

Alaska Department of Environmental Conservation
Division of Environmental Health
Solid Waste Program

#	Part Three: Landfill Records	POINTS Possible	POINTS Score
1	**PERMIT** – *A copy of the permit application and current permit must be kept in the operating plan.* 18 AAC 60.235 Is a copy of the permit application and current permit in the operating record? Yes	10	10
2	**OPERATIONS PLAN** – *The operations plan should be used as a guide for day to day operation of the landfill. A copy must be kept in the operating record.* 18 AAC 60.210, 18 AAC 60.235, permit Does the operating record contain a copy of the operations plan? Yes	10	10
3	**TRAINING** – *Landfill staff must receive training to recognize regulated hazardous waste and PCB waste. Records of training must be kept in the operating record.* 18 AAC 60.240 Does the landfill have a record showing that operators have received training to recognize regulated hazardous waste and PCB waste? Yes. All staff are current on multiple trainings including HAZWOP, Asbestos Abatement, HAZMAT	5	5
4	**RANDOM INSPECTION RECORDS** – *The landfill must perform random inspections of incoming waste loads to identify any regulated hazardous waste or PCB waste. Records of the inspections must be available for review.* 18 AAC 60.235, 18 AAC 60.240 Are random waste inspections performed and recorded? Yes. All loads are inspected as they are loaded and unloaded. A building survey is always done at site and recorded.	20	20
5	**ASBESTOS RECORDS** – *The landfill must maintain asbestos shipment records for each load of RACM. Records must include contact information for the waste generator and waste transporter, the amount (cy) disposed, and the date of receipt. The landfill must maintain an up-to-date map or site plan showing the boundaries of the asbestos cell. The landfill must maintain up-to-date records of the amount of waste in the RACM cell, including depth and the total volume.* 18 AAC 60.460 The permit was modified to include a RACM cell. However, no RACM has been received at the site yet so this is still Not Applicable until RACM is received. Does the landfill maintain complete asbestos shipment records for each load of RACM received? Does the operating record contain an adequate, up-to-date map of the asbestos cell? Does the operating record contain up-to-date information about the depth and total volume of RACM in the asbestos cell?	NA	NA

Inert Waste Monofill Inspection Checklist

Alaska Department of Environmental Conservation
Division of Environmental Health
Solid Waste Program

#	Part Three: Landfill Records	POINTS Possible	POINTS Score
6	**VISUAL MONITORING** – *Visual monitoring must be performed at least monthly and recorded on a form approved by ADEC. Records must be maintained for at least 5 years.* 18 AAC 60.800 Does the operating record contain copies of monthly visual monitoring reports? Yes, since opening. [X] Violations of permit conditions, or regulatory requirements [X] Settlement [X] Ponding [X] Leakage [X] Thermal instability (permafrost landfills only) [X] Frost action [X] Erosion [X] Signs of damage to due to operations [X] Damage to monitoring devices [X] Escape of leachate [X] Escape of waste [X] Unauthorized waste disposal [ ] Wind blown litter [X] Damage to a containment structure, retaining wall, erosion control, or diversion structure [X] Fire or combustion in the waste [X] Impacts to fish, wildlife, or vegetation [ ] Any other conditions that threaten public health or the environment:	10	10
7	**COST ESTIMATES AND FINANCIAL ASSURANCE** – *The landfill may need to update closure and post closure cost estimates annually to adjust for inflation. The landfill may need to demonstrate financial assurance to cover closure and post closure costs if monitoring is being done. The local government financial test is the most commonly used mechanism. Documentation must be kept in the operating record. Some financial assurance mechanisms require an annual update.* 18 AAC 60.235, 18 AAC 60.285 Does the operating record contain appropriate and up-to-date (i.e. annual) closure and post-closure cost estimates? Does the operating record contain appropriate and up-to-date financial assurance documentation? What is the date of the latest estimate? _____	NA	NA
8	**AS-BUILT DRAWINGS** – *The facility is required to maintain as-built drawings in the operating record.* 18 AAC 60.235 Does the operating record contain as-built drawings? Yes	5	5

Inert Waste Monofill Inspection Checklist

Alaska Department of Environmental Conservation
Division of Environmental Health
Solid Waste Program

#	Part Three: Landfill Records	POINTS Possible	POINTS Score
9	**MONITORING PLAN** – *If the facility is monitoring groundwater or surface water, it needs a plan to be kept in the operating record.* 18 AAC 60.810, 18 AAC 60.830 Is the facility required to monitor surface water or groundwater? If so, is the monitoring plan in the operating record?	NA	NA

Part Four: Landfill Development

This section should be completed at the landfill facility during the site visit.

#	Part Four: Landfill Development	POINTS Possible	POINTS Score
1	**LANDFILL DEVELOPMENT** – *The facility is required to follow the approved landfill site plans and development plans. If minor changes are made, they should not be detrimental to regular operations. Any major changes must be approved by ADEC.* 18 AAC 60.233, 18 AAC 60.210, permit Is the facility following the site and developments plans? Yes If any minor changes have been made, are they detrimental to operations? NA Is the waste disposal area at least 50 feet from the property boundary? Yes	30	30
2	**WATER WELLS** – *Waste may not be disposed of within 500 feet of a drinking water well. If any wells exist within 500 feet of the property boundary, the site must be developed and operated to ensure that waste is not deposited too near the wells.* 18 AAC 60.040 A new survey indicated that a drinking water well identified on the previous surveys was actually not a well. Therefore, no drinking water wells are located within 500 feet of the landfill boundary. Has development of the landfill or surrounding area impacted this separation zone?	NA	NA

Part Five: Access

This section should be completed at the landfill facility during the site visit.

#	Part Five: Access	POINTS Possible	POINTS Score
1	**SIGNAGE** – *A clearly legible sign must be posted at the entrance to the landfill. The sign must prohibit disposal of regulated hazardous waste and polychlorinated biphenyl (PCB) waste. Most permits also require signage that identifies the owner or operator, hours of operation, and emergency contacts.* 18 AAC 60.240, permit Are signs prohibiting hazardous waste and PCB waste posted and clearly legible? Yes If additional signage is required, is it posted and clearly legible? Yes Do the existing signs meet all of the requirements noted in Part One, Question 6? Na	5	5

Inert Waste Monofill Inspection Checklist

Alaska Department of Environmental Conservation
Division of Environmental Health
Solid Waste Program

#	Part Five: Access	POINTS Possible	POINTS Score
2	**ACCESS** – *Access to the landfill facility must be limited by the use of fencing, berms, or natural barriers to control public access to the site. This should prevent unauthorized traffic or dumping.* 18 AAC 60.220 Is access to and within the facility limited? Yes. Locked gates at entrance. Is there any evidence of unauthorized access to the landfill (target shooting, off-road vehicles, etc) No Is there any evidence of dumping outside the permitted areas? No	20	20

Part Six: Working Cell Operations

This section should be completed at the landfill facility during the site visit.

#	Part Six: Working Cell Operations	POINTS Possible	POINTS Score
1	**AUTHORIZED WASTE TYPES** – *The landfill is required to have a permit that authorizes all types of waste disposed at the site.* 18 AAC 60.200 Is there evidence that the facility has accepted or is accepting any wastes that are not addressed or authorized in the permit? *(See answers in Part One, Question 5)* No	20	20

Part Seven: General Operations

This section should be completed at the landfill facility during the site visit.

#	Part Seven: General Operations	POINTS Possible	POINTS Score
1	**LITTER** - *Litter must be controlled so that it does not become a nuisance or hazard and must be removed from access roads and other areas of the facility.* 18 AAC 60.233, 18 AAC 60. Is excessive litter evident at or near the landfill? No, none at all. Check the types of measures that are used to control litter at the landfill: [X] Litter fencing [ ] Litter collection [ ] Other _____	5	5
2	**DUST, ODOR, NOISE, ETC.** - *Dust, odor, noise, traffic, and other effects from the landfill must not become a nuisance or hazard to the public health, safety, or welfare.* 18 AAC 60.233 Are dust, odor, noise, traffic or other effects from the operation causing, or likely to cause, a nuisance to neighboring homes or businesses? No.	5	5

Inert Waste Monofill Inspection Checklist

Alaska Department of Environmental Conservation
Division of Environmental Health
Solid Waste Program

#	Part Seven: General Operations	POINTS Possible	POINTS Score
3	**SALVAGING** - *Public salvaging, if allowed, must be limited to an area that does not hinder facility operation, create a safety hazard, or cause pollution.* 18 AAC 60.220 This facility does not have any public salvaging. CRS (the operator of the landfill) does have a nicely organized laydown/reuse area where reusable/recyclable materials are stored. These materials are used by the company on other projects or sold. Is public salvaging restricted to a controlled area away from the working face? Is the salvage area managed with respect to safety and pollution control?	NA	NA
4	**DISEASE VECTORS AND ANIMALS** - *Disease vectors, including wildlife and domestic animals, must be controlled so that the public health, safety, or welfare are not endangered by the spread of disease or contact with animals, and that the animals are not harmed by contact with the waste or become a nuisance.* 18 AAC 60.230 Is there any evidence (prints, scat, digging, etc.) of bear, fox, or other animals around the waste? No Were there excessive numbers of birds present? None Are there any reports of wildlife being harmed, or conditions that are likely to harm wildlife? No	5	5
5	**INACTIVE AREAS** - *Areas that have not received waste for more than 90 days, but have not yet reached the final capacity or elevation, must receive an intermediate cover. The area must be covered with 12 inches of soil and graded to prevent ponding and erosion.* 18 AAC 60.243 Have inactive areas been appropriately covered and graded? Yes	10	10
6	**MAINTENANCE AND REPAIR** - *The landfill must maintain structures and components of the facility, and repair any structural changes or damage to the facility.* 18 AAC 60.815 Are there signs of damage to any component of the facility? No	10	10

Part Eight: Special Waste

This section should be completed at the landfill facility during the site visit.

Inert Waste Monofill
Inspection Checklist

Alaska Department of
Environmental Conservation
Division of Environmental Health
Solid Waste Program

#	Part Eight: Special Waste	POINTS Possible	POINTS Score
1	**RACM CELL-** *If the facility accepts RACM, it must be disposed of in a separate cell. Access to the asbestos site must be restricted, and there must be no visible emissions.* 40 CFR 61.154 *Asbestos loads must be inspected and handled to insure that all friable asbestos is sealed in leak-proof containers, deposited in the asbestos cell without damaging the containers, and covered by the end of the day with 6 inches of soil.* 18 AAC 60.450 **This question is currently not applicable but will be once RACM is received** Is RACM disposed of in a separate cell from MSW? It will be once it is received. Is there evidence of visible emissions? NA What measures are used to prevent public access to the asbestos disposal area? The site is not open to the public, locked gate at entrance, asbestos cell will be completely fenced with required signage. Are any exposed or broken bags evident? NA Has adequate cover been applied to the waste? NA	NA	NA
2	**NON-RACM HANDLING** - *Non-RACM waste must be handled so that it does not become friable. It must be covered within 24 hours using procedures that prevent the release of asbestos fibers.* 18 AAC 60.450 Does the facility handle non-RACM waste so that it does not become friable and does the facility cover it within 24 hours? Yes	10	10
3	**LIQUID WASTE** - *Liquid waste may not be disposed at the landfill, with the exception of small quantities (one gallon or less) of containerized household waste. This includes leachate and baler squeezings, unless recirculation has been approved under an RD&D permit.* 18 AAC 60.420 Are any prohibited liquids disposed at the landfill? No Are any fluids generated at the landfill (leachate or baler squeezings)? No If so, how are they disposed? Na	10	10
4	**VEHICLES** - *Vehicles may not be disposed at the landfill unless all fluids and batteries have been removed. If undrained vehicles, or the fluids and batteries removed from them, are stored at the landfill for later disposal or recycling, they must be managed to prevent release of fluids.* 18 AAC 60.335, 18 AAC 60.010 Are vehicles disposed at the landfill? No Are all fluids and batteries removed prior to disposal? Na	NA	NA

Part Nine: Surface Water Controls/Impacts

This section should be completed at the landfill facility during the site visit.

Inert Waste Monofill
Inspection Checklist

Alaska Department of Environmental Conservation
Division of Environmental Health
Solid Waste Program

#	Part Nine: Surface Water Controls/Impacts	POINTS Possible	POINTS Score
1	**RUN-ON/RUN-OFF** - *The landfill must have a control system to prevent run-on water from flowing into the active cell.* 18 AAC 60.225 Does the control system prevent run-on from flowing into the active cell? Yes Is there evidence that run-off may be impacting nearby waters? No	10	10
2	**SURFACE WATER AND PONDING** - *Waste may not be placed in surface water, including ponded rainwater. Landfill surfaces should be graded to prevent ponding, and all ponded water must be removed within 30 days.* 18 AAC 60.225 Is there any evidence of waste in contact with surface water, including ponded rainwater? No	5	5
3	**LEACHATE SEEPS** - *Leachate seeps must be prevented, or contained and controlled at the boundary of the waste management area if the department finds it necessary.* 18 AAC 60.225 Has the department found it necessary to contain or control leachate seeps? No Are there any visible leachate seeps outside the landfill cell? No What measures have been taken to contain and control the seeps? Na	30	30
4	**PERMAFROST** - *If the landfill is located on permafrost, it must be designed and operated so that the permafrost remains frozen. If the landfill settles and water is pooling, the operator must take corrective action.* 18 AAC 60.227 Are there any indications that permafrost is thawing (pooled water or settlement)?	NA	NA

Part Ten: Monitoring Locations

This section should be completed at the landfill facility during the site visit.

#	Part Ten: Monitoring Locations	POINTS Possible	POINTS Score
1	**MONITORING LOCATIONS** – *Monitoring, if done, must be conducted at approved locations. Surface water monitoring sites must be properly maintained. Groundwater monitoring wells must be properly maintained.* 18 AAC 60.810, 18 AAC 60.825, permit Are surface water monitoring sites clearly identified and marked? Are surface water monitoring sites located according to the approved plan? Are monitoring wells in good condition and locked? Are other monitoring devices well maintained and located as required?	NA	NA

Part Eleven: Additional Permit Requirements

This section should be completed at the landfill facility during the site visit.

Response to City of Palmer Resolution

Dear Ms. Lee:

On November 25, 2014 The City of Palmer passed a resolution 14-038 requesting the MSB not approve the CMS, Conditional Use Permit application presently before the MSB Planning Commission. Central Monofill Services, (CMS) refutes the conclusions stated by the City of Palmer, (Palmer) in this resolution as they appear to be primarily based on opinions, not facts. Based on the conclusions and testimony of City Council members it is clear they have not thoroughly reviewed the CMS CUP application presently before the MSB.

Let's look at the inaccuracies and misconceptions in the resolution:

1. The resolution indicates we incorrectly identified the adjoining City property as industrial. The resolution doesn't identify what the City thinks is the correct land use designation, but the MSB has no zoning or land use definitions. CMS chose to identify this property as industrial since a large portion of the City property has been mined for gravel and leasing agricultural property is an industry. The farmhouse is unoccupied.

2. The City says it is concerned with the applicant's credibility given the Borough issued citations to "Central Environmental Services which operates Central Recycling Services and Central Monofill Services". Central Environmental, Inc., Central Recycling Services and Central Monofill Services are independent companies whose business structure and working relationship are clearly identified within the CUP package. Central Environmental, Inc. and Central Recycling Service were not issued any citations. Central Monofill Services was issued 3 citations, not six. These citations are currently under appeal.

PH (907) 770-7470 FAX (907) 770-5084
www.centralmonofillalaska.com • cms@centralmonofillalaska.com

3. The resolution says the Monofill will not meet the Alaska Department of Environmental Conservation requirement that the base of the Monofill be at least 10 feet above groundwater. This is incorrect and clearly shown and discussed at great length in the CUP package.

4. The resolution says there is potential for contaminants to travel off the property, however, they provide no documentation to support this statement. Please see the four expert's reports within the CMS CUP package which provide extensive documentation that refutes this unfounded allegation.

5. The City resolution indicates the CUP is not consistent with a goal of the Palmer Comprehensive plan. The subject property is not within the City of Palmer. The same statement indicates approval of the CUP will degrade the visual quality of the Glenn Highway which is unfounded since the MSB Code requires the operation be screened from view of the Glenn Highway and ROW. This screening requirement and proposed screening methods are described in detail in the CMS CUP application. The CMS operations within the CUP area will be screened from public view.

6. Another concern raised by the council in the resolution is debris will blow from the site and detract from the Scenic Byway experience. This issue was raised by MSB staff and CMS has addressed measures to control blowing debris in great depth within the current CMS CUP package. While Palmer has raised the issue of blowing debris they fail to note that they placed no restrictions on the City of Palmer, AK Demo Monofill CUP. The AK Demo Monofill supported by Palmer has not had reported issues with debris blowing from the site

7. The resolution indicates a future ADOT project may remove a berm from the property causing unsightly entry to the City. This has been addressed in the CMS CUP package, In summary should any screening be removed due to future ADOT projects it would have to be replaced per the requirements of the CUP therefore the operations will still be screened from view by the public.

8. Per the City of Palmer resolution, *"WHEREAS, the operation of the Alaska Demolition Construction & Demolition landfill does not include the sorting, collection, and sale of salvageable, reusable material on site similar to a junkyard and is therefore not a good comparison to the operation of the proposed inert material Monofill."* This does not make any sense. Per MSB code if the AK Demo Monofill were in the MSB, both operations would require a 17.60 Junkyard CUP. Both operations require the same ADEC permit. Both operations handle the same type of Construction & Demolition material. How are they not a good comparison? The only difference is the proposed CMS operations operates with many more controls and works to recycle and reduce how much of the same C&D material has to be thrown away.

The City of Palmer in its December of 2013, findings of facts to renew the AK Demolition Monofill CUP found; **"The conditional use will preserve the value, spirit, character and integrity of the surrounding area:", "Granting the conditional use permit will not be harmful to the public health, safety, convenience and comfort of the neighborhood."**

The City of Palmer's Resolution NO. 14-038 recommending disapproval of the CMS CUP before the MSB Planning Commission is not only based on numerous unfounded and unsupportable allegations, it also directly contradicts their action in approving a CUP for a similar Monofill CUP within the City of Palmer.

During the most recent renewal hearing for the AK Demo Monofill CUP that I attended, Council members expressed concern that the AK Demo Monofill was not being filled quickly enough. The City wants this property filled for additional Alaska State Fair parking. Passing this Resolution by the City of Palmer is hypocritical at best and designed to prohibit competition for the City of Palmers Monofill at worst.

Should you have any further questions or require further clarification please do not hesitate to ask.

Respectfully,

Shane Durand

To: Durand, Shane
Subject: Siezmic evaluations of existing ground surface

Shane,

When we did our initial response to the MSB question (#23) requesting siezmic evaluations, we contacted Keith Mobley, PE, the civil engineer who did the seismic evaluation of the perimeter berms. We asked him to evaluate the existing topography as well. After a review of the general site conditions, he did not see any specific area of concern. He was willing to discuss any specific concern anyone has. Borehole data from the south part of the ponds show the soils to be predominately gravel and sand with silt. (see Test boring log #3 and #4 attached for typical soils, #4 is the further south log) This type of soil is not likely to liquefy. After our verbal consultation with Mr. Mobley we gave the following response to question 23.

"The existing site is not vulnerable to significant impacts from a large earthquake due to topography, soil types or ground water. The ground water is below the relatively flat bottom of the monofill, so there are no saturated soils that could liquefy and the flat bottom does not have areas for material to slough to. The monofill is designed with setbacks keeping the monofill away from the ponds so even if a slope were to fail the waste material would not reach the ponds."

J. A. MUNTER CONSULTING, INC.

December 1, 2014

Re: Testimony to MSB Planning Commission about an application for a Conditional Use Permit for a proposed monofill near Palmer, Alaska

Members of the Board,

My name is Jim Munter. I am the Principal Hydrogeologist at J. A. Munter Consulting, Inc. Since my most recent submittal in February 2014, there have been some responses to my work and the borough Staff has prepared their analysis and recommendation in your packet. I was requested last week by the borough to review all of that information and provide additional comments as warranted by the record here tonight. I have not been involved in any technical discussions with the Borough or reviewers of my work between my submittal last February until today.

A great volume of complicated technical analysis is before you.
Time limits prohibit me from detailed rebuttal or discussion tonight.

Although a few sections of my prior reviews that would benefit from some minor revisions, I have found no compelling technical case to substantially revise or retract any of my prior comments.

The record still contains significant technical deficiencies that preclude supporting the statement found in the Borough findings, that this facility does not have the potential for groundwater contamination that could have negative effects on drinking water.

For example, Maddox, Terrasat, and the Borough misinterpreted evaporation data to conclude that the site is semi-arid. I do not agree with that interpretation. The US Geological Survey, in a recent and fully peer-reviewed report, characterize the site as transitional between maritime and continental climates. Maddox, Terrasat, and the Borough further conclude that as a result of the semiarid climate, recharge will not occur or be minimal at this site. The USGS estimates that 1.4 inches of water per year will recharge groundwater at this site, which equates to more than 1 million gallons of water. This is a significant volume of water to percolate through the waste material and enter the groundwater system.

HANDOUT

5701 PENNY CIRCLE, ANCHORAGE, AK, 99516
jamunter@arctic.net
PHONE (907) 345-0165; FAX (907) 348-8592

Second, Terrasat's modeling understates potential groundwater contamination because it assumes that when leachate is generated, it mixes instantaneously with the entire volume of groundwater beneath the site. This is not what typically happens.

Thirdly, the Terrrasat analysis makes extensive reference to the final "silt cap" over the site. There is no requirement for a silt cap. Condition 21 should be revised to require a silt cap with a permeability no greater than 10-4cm/sec throughout the entire cap. This is what Terrasat used in their modeling. there should also be a sufficient field testing and verification program to prove that it gets properly installed and maintained.

Fourth, the Borough has proposed using Terrasat's groundwater monitoring plan from 2013. this plan contains major deficiencies that I previously commented on and that have not been fixed. But it is fixable. For example, the section line easement that cleaves the site looks like it might be an excellent location for a few monitoring wells.

Finally, this facility projects that the final compacted fill structure will be stable. Potential settlement of the pile and ponding of water on the final cap is a significant potential issue. The technical analysis supporting the stability of the pile is quite limited. I suggest a minimum five-year post-closure monitoring and remediation plan. This is because remediation of settlement and the prevention of ponding on the cap are critical factors for the long-term prevention of groundwater contamination at this site.

I would be happy to answer any questions.

Received

CITY OF PALMER, ALASKA

Resolution No. 14-038

A Resolution of the Palmer City Council Requesting the Matanuska-Susitna Borough Planning Commission Deny a Conditional Use Permit for the Operation of an Inert Material Monofill on MSB Parcels 17N02E18C010 and 17N02E19B006

WHEREAS, the City of Palmer is the owner of MSB Parcel 17N02E18D002 located adjacent to the proposed Conditional Use Permit for operation of an Inert Material Monofill to be considered by the Borough Planning Commission on December 1, 2014; and

WHEREAS, the applicant's map of Proposed CMS Site Showing Adjacent Property Types incorrectly identifies the City's parcel which contains a farmhouse and leased agricultural field as an Industrial use; and

WHEREAS, the City is concerned with the applicants credibility given the Borough issued six citations charging Central Environmental Services which operates Central Recycling Services and Central Monofill Services with illegally dumping material on MSB Parcels 17N02E18C010 and 17N02E19B006 prior to approval of a Borough permit; and

WHEREAS, according to the Central Monofill Services' application not all of the actual monofill site will meet the Alaska Department of Environmental Conservation requirement that the base of the monofill is at least 10 feet above groundwater; and

WHEREAS, given the unpredictable water table underlying the proposed site due to earlier penetration of the underground aquifer, there is a potential for contaminants from the monofill to travel off the property to area wells and lakes; and

WHEREAS, the application shows that 35.5 acres of the 52 acre site will be used for the monofill and 16.5 acres will be used for recycling operations; and

WHEREAS, the 16.5 acre recycling area will include outdoor collection and storage of salvageable and reusable material such as scrap metal, broken concrete, wood, tires and recyclable windows and HDPE pipe; and

WHEREAS, an inert landfill should not become a model of the reclamation of landfills in the area; and

WHEREAS, the outdoor storage of this salvageable and reusable material is generally categorized by the Borough as a "Junkyard"; and

WHEREAS, the establishment of a new junkyard adjacent to the Glenn Highway is inconsistent with maintaining the Glenn Highway corridor as an attractive community entry to Palmer which is Goal 1, Chapter 5 of the current Palmer Comprehensive Plan and Goal 7, Chapter 6 which is to maintain and improve the visual quality of the Glenn and Palmer-Wasilla Highways corridors, and other major community roads; and

WHEREAS, this region experiences frequent multiple-day high- wind events each year since it is at the confluence of the Matanuska and Knik River valleys and loose debris and dust from the fill has and is expected to continue to scatter beyond the boundaries of the site which is incompatible with the Glenn Highway National Scenic Byway designation of this section of the Glenn Highway; and

WHEREAS, the berm currently screening a portion of this site from the Glenn Highway, may be removed as the Glenn Highway is expanded to four lanes as proposed by the Alaska Department of Transportation further causing an unsightly entry into the City and reducing the value of the Glenn Highway National Scenic Byway experience for travelers; and

WHEREAS, the Inert Material Monofill application submitted by Central Monofill Services refers to the Alaska Demolition Construction & Demolition landfill located in the Palmer City limits which has had a Conditional Use Permit; and

WHEREAS, Alaska Demolition Construction & Demolition landfill is located on a minor community road that is not visible to the travelling public and is approved to fill a pit left by a former gravel operation without stacking cells to a level above the ground level of the adjacent property; and

WHEREAS, the operation of the Alaska Demolition Construction & Demolition landfill does not include the sorting, collection, and sale of salvageable, reusable material on site similar to a junkyard and is therefore not a good comparison to the operation of the proposed inert material monofill.

NOW, THEREFORE, BE IT RESOLVED by the Palmer City Council that it requesting the Matanuska-Susitna Borough Planning Commission not approve a Conditional Use Permit for the operation of an Inert Material Monofill on MSB Parcels 17N02E18C010 and 17N02E19B006.

Passed and approved by the City Council of the City of Palmer, Alaska this twenty-fifth day of November, 2014.

DeLena Goodwin Johnson, Mayor

Janette M. Bower, MMC, City Clerk

Subject: incorrect finding in the staff recommendation.

HANDOUT

Hi Alex and Susan,

Just as a followup to our conversation with Alex on Wednesday, Nov. 26, it took me awhile to find it. But staff's findings (p. 69) include the statement that "Documentation has been provided demonstrating that the monofill operation does not have the potential for groundwater contamination that could have negative effects on driving water and surface water quality."

This is not an accurate reflection of the record. What the record shows is that documentation has shown that there is dispute about whether groundwater contamination could occur that would have negative impacts. Without a qualified hydrologist on staff, it's inaccurate to make the statement that this doesn't have the potential to impact groundwater.

- Stephanie Nowers.

P.S. Please also consider this email to be submitted to the planning commission, if possible.

Subject: Request for DNR to be present at tonight's Planning Commission meeting

HANDOUT

Hi folks,

I'd like to request that the borough ask DNR to be present at the Planning Commission hearing tonight on the Conditional Use Permit request from Central Monofill Services for a dump site at Mile 38.3 of the Glenn Highway. Specifically to have folks from the Water Resources Section be present so that the record can be clear as to the status of DNR's work regarding the connection between the gravel pit ponds and area lakes and wells. In addition for DNR to be present to state their efforts to date to get CMS to repair the spillway that was installed between the two gravel pit ponds. The spillway is relevant because fixing it could alter the groundwater table where the dump is proposed. At one point, 1.4 million gallons A DAY was flowing through the spillway. The repair that is needed would reduce or eliminate that flow completely. This is key information for the planning commission to consider before deciding on this permit. In addition, CMS has stated that DNR has "not corroborated" the connection between the ponds and the lakes. That is true but not because it has been disproven. Rather DNR's work to date has not had enough time to rule out other possibilities.

Again I apologize for the short notice. I am copying David Schade and Charles Cobb from the Water Resources Division on this request.

Thank you,

Stephanie Nowers

Subject: Re: Meeting this week

HANDOUT

Hi folks,

I'm disappointed no one is available to talk to, and I will submit written comment for the meetings.

In the interim, I'd request that the borough ask hydrologist Jim Munter to be present at the Dec. 1 Planning Commission hearing to answer any questions the planning commission might have about his hydrology reports to the borough. Munter, in two previous reports for the borough, concluded that the monofill as proposed posed a significant potential to contaminate groundwater and area wells. The borough in its staff report finds that the monofill has minimal potential for leachate and that there will be no contamination plume based on studies done by hydrology experts hired by CMS. Munter had reviewed those reports and still concluded there was significant potential for contamination. I'm assuming the borough does not have its own hydrologist available to review the conflicting hydrology reports. In light of that and because the uncertainty about the hydrology of this property is so key to the determination of whether the proposed operation poses a threat to public health, safety and welfare, I respectfully request that the borough in the interest of a full discussion provide the Planning Commission access to Mr. Munter for questions that may arise as well as the other hydrology experts if needed. FYI: I did speak with Mr. Munter this morning. He has reviewed the other hydrology reports provided by CMS, and he has not changed his opinion that as proposed this operation poses a significant potential to contaminate groundwater and area wells.

I apologize for the short notice of this request in a holiday week. However, the packet for the meeting has been on short notice as it was just posted online yesterday.

Thank you for your consideration.

- Stephanie Nowers

Subject: Meeting this week

Hi Susan,

A few of us would like to meet with you and maybe other planning staff this week in advance of the hearing on Monday. Do you have time today?

We're looking for clarification on the hydrology review as it appears staff decided to reject Munter's conclusions and it's not clear why. We also have additional information from Ohio that is relevant given staffs findings but are unsure how to submit it. Finally if you have the page numbers for the water quality monitoring plan submitted by CMS, I still have not been able to find it in the packet. Sorry for the short notice. But working as fast as we can as we just got the packet yesterday.

Happy almost thanksgiving,

Stephanie

according to common experiences. The geometry of the Payatas dumpsite seems to have met the slope requirement, showing slopes of about 1:3 with a height of 25-40 metres. However, some specific conditions that are particularly true in tropical developing countries were apparently not considered thoroughly:

The collapsed slope of the Payatas landslide four weeks after the event

- low density of waste - due to a high portion of light plastic materials and insufficient waste compaction
- unrestricted water percolation - water percolation usually decreases with the presence of paper. Observation has shown a lack of paper due to the outstandingly high recycling ratio
- extremely high rates and non-uniform distribution of rainfall.

The major reason for the landslide was the low waste density resulting from the composition of waste delivered to the Payatas dumpsite. The waste material was characterized by a high proportion of plastics and organics and a total absence of other materials (paper, glass, metals). MSW with this composition is resistant to conventional compaction methods, even using heavy equipment. The waste composition in Manila is typical for urban areas in developing countries and countries with emerging economies. Basically, this results from an extraordinary consumption of plastics as packaging material, a lack of recycling systems for organic waste and an outstandingly high recycling rate for reusable materials. The high recycling rate primarily reflects the country's poverty, which forces people to earn their living by segregating waste at dumpsites. The impact of low waste density on landfill stability was amplified by heavy rainfall, which is characteristic for the tropical location. The low waste density reduced the surface flow of rainwater and evaporation, resulting in a high rate of water infiltration. Landfill leachate decreased the shear strength of waste by mobilizing pore water pressure and flow pressure, finally triggering the failure. The settling of waste, due to the high content of organic materials, was also driving this effect.

Athens, Greece, March 2003

The municipal solid waste of the Greek capital Athens is disposed at several landfills in the metropolitan area. One of these is the landfill in Ano Liossia, located 10 km north of downtown Athens. This site is operated by the public agency ΕΣΔΚΝΑ (in English, ACMAR, the Association of the Communities and Municipalities of the Attiki Region). The dumping area amounts to approximately 0.5 km^2, and its height varies from about 60 to 80 metres. The site is surrounded by chains of hills, opening to the north to the Attiki plain.

In March 2003 the eastern slope of the landfill failed and cracked down, covering the 20-metre-deep notch between the slope and the recycling facilities with waste.

Approximately 800,000 m^3 of waste moved, leaving a 300- to 400-metre-wide gap in the slope behind.

July 10 2000 PAYATAS PHILIPPINES

Landfill failure in Athens, Greece. In this landslide, about 800,000 m^3 of waste moved, leaving a 300- to 400-metre-wide gap in the slope behind

A detailed forensic analysis is not available yet. Water is very likely to be a cause as it is in all cases of landfill failure, but no significant water outlet from the failing slope has been reported by the operator. This point makes the case even more interesting, since landfills in arid and semi-arid areas have not been endangered unless the internal water balance is massively disturbed. Since the landfill has been constructed according to current European standards with liner and drainage systems, there was no reason to expect waterborne stability problems. It hasn't become finally clear why the slope failed. It may also be a consequence of a fire, which occurred two weeks before in the landfill stretch concerned. Landfill fires are extremely dangerous for stability; smouldering fires, which do not burn with open flames on the surface, are especially dangerous. A smouldering fire may feed its way to deeper waste layers, leaving plastics and paper burnt and sweeping their reinforcement effect away. Fighting smouldering fires with water may even double the problem, because the fire is pushed forwards while the water level inside the landfill may increase.

Waste mechanics

It is well known to many landfill operators that waste has an extremely high strength, even enabling the construction of vertical temporary slopes. However, it is essential to understand what the material's strength is based on in order to evaluate landfill stability realistically. If the geotechnical engineer is not able to conduct an appropriate stability analysis specifically reflecting the strength characteristics, then the factors limiting safety can never be identified and the operators may carry out bad operating measures. As a consequence, more failures will happen.

Background

Municipal solid waste shows strength characteristics that are considerably different from soils. MSW strength is determined by the fibres and foils contained in the waste. These components produce an effect similar to reinforcement. Just like reinforced soil, the shear resistance of MSW takes into account the friction between the granular particles and the tensile forces in the fibrous components. The shear resistance due to reinforcement effects is called fibrous cohesion. The fibrous cohesion generated by tensile stress in the fibres depends on the normal stress (load). Therefore, shear strength increases with the depth of the deposit. The total shear strength resulting from friction and reinforcement is much higher than the shear strength of soil.

The eastern slope of the Ihlenberg landfill, where the cessation of waste dumping had caused a depression in the landfill's geometry

Because waste is normally placed in the landfill in roughly horizontal lifts, the fibrous components are directed

ASBESTOS

There is no independent inspection process to assure proper asbestos containment at this PRIVATELY OWNED, FOR PROFIT dump. The Palmer dump already has an asbestos cell and C&D (construction and demolition) section with proper oversight. AK Demo already runs a private C&D dump 2 miles away.

POISON WELLS UP TO A MILE FROM THE SITE

A borough sponsored hydrological evaluation concludes: "Contaminants could travel approximately a mile down-gradient and still exceed drinking water standards". A quote from CT.gov states, "wood waste from construction, renovation and demolition, pressure treated timber … may contain creosote, lead, acrylic, chromium, pentachlorophenol, phenol-formaldehyde resins, and other known carcinogens and ground water contaminants…. These pollutants can leach into the ground water" (http://www.ct.gov/deep/cwp/view.asp?a=2718&q=325342)

ENVIRONMENTAL CRIME HISTORY

While being cited for **illegally dumping** waste without a permit or even a business license, CMS Corporate Officer Shane Durand stated, "the solution to pollution is dilution." The company was later fined and were repeatedly ordered to clean up although they claimed the dumped material was not trash-see photo.

(MSB Code compliance case summary G20130022 page 5—Read the official report at PalmerToxicDumping.Org)

CONTAMINATION OF FISHING IN THE KEPLER-BRADLEY LAKE SYSTEM

The site sits on top of the open aquifer that flows through fishing and recreation areas at Canoe Lake, Kepler-Bradley Lake, and beyond. Approval of a combination dump & junkyard permit for this property will allow fuel tanks and potentially leaky equipment to be parked on the edge of man-made gravel pit lakes OPEN TO THE AQUIFER.

WINDBLOWN TRASH

"Valley Trash" *will* be what people see on their way to Palmer. That affects tourism, business, property values and tax revenues.

PalmerToxicDumping.Org

Junkyard permit will allow fuel tanks next to gravel-pond lakes that feed directly into wells and our aquifer

Public Comment to Planning Commission

Dear Planning Commission

We live on Canoe Lake and are opposed to Central Monofil's permit for a private dump at mile 38.3 of the Glenn Hwy.
This dump presents threats and hazards to the local surrounding area: Health, drinking water, lakes, fish, environment, natural habitat, wild life, air quality, and devastating results in the event of an earth quake or fire. It will be an eye sore, reduce property values in the region, and will be a detriment to our otherwise pristine national scenic byway.

Water quality is vital: It is the worst location for a monofil in the whole Matanuska/Susitna Valley because the site sits on top of the massive aquifer that feeds our lakes and provides drinking water. People with wells that are connected to the aquifer will not have confidence in drinking the water that once had no threat of pollution. The aquifer is connected to the water that feeds the surrounding lakes. The Kepler/Bradley Lake Systems and and Matanuska Lake Recreation area will be under threat of irreversible contamination. Local residents and tourists alike enjoy fishing in the pristine unpolluted waters in the rivers and lakes in the close surrounding area. With the threat of the dump that could contaminate the lakes it will detour recreational fishing in the area. When the lakes are contaminated it will pollute and possibly wipe out our fragile eco system and kill fish, waterfowl, birds of prey and wild life that live around and in the lakes. We have nesting eagles and osprey who hunt in this region. Central Monofill has not regulated the water levels in the ponds in order to protect the water levels in the surrounding lakes. How can we trust that they will protect the water quality?

. A dump permit would allow tanks and potentially leaky equipment to be parked next to the ponds open to the aquifer. Accidents happen. The aquifer is only 2 feet below the surface and even if they

state there is 10 feet, how can microscopic pollutants be filtered out in just 10 feet, Even if they line the dumping cells, they will have to pump them out – who will regulate this procedure to protect any spillage into the ponds or grounds. Where will they dump this toxic fluid?
ASBESTOS, HEALTH CONCERNS:, Cancer from asbestos is life threatening! Who will monitor the owners to make sure they dump the asbestos safely. Those who live close by are asked to take a drastic health risk and trust our lives and in the professional credibility of the monofill owners and staff. They to date have already been sited for not complying with contracts and codes. How can they be trusted? It will be cost prohibitive to pay borough staff to their monitor dumping practices, so they will be dumping without accountability and monitoring. Accidents happen and the local residents will suffer irreversible health issues as a result.
The dump is in a wind tunnel that can get winds up to 80 mph that snaps trees and tears roofs off of houses and causes substantial damage to structures. These winds will blow any trash that has not been covered adequately, and blow not only trash but air pollutants causing health hazards. It will harm those with lung issues such as asthma, emphysema etc.
CMS also wants to store and sell salvaged items and materials and vehicles & who knows what else? There will be stacks of vehicles, and junk that may also leak and pollute. Do we want a "Sanford & Son's" junkyard at our gateway and along our scenic byway, and down the highway from our new visitor center! This will be a detriment to our image and make us live up to the name of Valley Trash. We will be a joke and Anchorage will be laughing as we store and dump there trash in our front door!!
The borough would make so much revenue if they had to pay to dump in borough dumps. What is the reasoning that would cause the borough to let them create an eye sore and health hazard when they could be making money from these folks. If they want to bring Anchorage trash here they should pay like everyone else!!!
What happens WHEN there is an earthquake? The 64 earthquakes damaged our wetlands and rocked this area too!!! We have had some significant earthquakes in the last few months in the valley. I live just blocks away from the dump and our house was rocking and shaking.
The monofill site was supposed to have been developed into a beautiful subdivision for lakefront homes. There was only one problem… The soil in this earthquake zone is too unstable for building. The sand will liquefy in an earthquake. It may also subside as the hay flats did during the 1964 earthquake.
The CMS site is too unstable to support a house, but it is being planned to support a chemical containing waste pile 8 stories high. With the groundwater at ground level currently and many earthquakes to come, we could easily end up with a site that has acres of waste continuously leaching directly into groundwater.
What if there is a wild fire?? The toxic garbage and tires will heavily pollute the air and environment. This is a "NO BRAINER" anyone who votes r to approve the CMS dump application is either mentally unstable or "bought off" by CMS – in either case they should be removed from the Planning Commission. The community is watching and trusting the Planning Commission to make a decision on what is best for the communities health and well being and image. Will the Planning Commission vote for what is best for Valley residents or for questionable a Anchorage business.

We support the plan that was created and approved by the community which preserves this area for a a beautiful park or something that will benefit our community and compliment our National Scenic Byway, and be a beautiful welcome to our Valley that is just up from our new visitors center.

Sincerely

Geri McCann

Subject: NO to CENTRAL MONOFIL !!!

I am writing to voice my opinion "NO!!" on the toxic dump in Palmer.
We do not need Anchorage trash here.
I have property right there by the fair grounds that is farm and or future development.
It is on Inner Springer Loop.

I vote a serious and loud "NO" to that proposed toxic waste dump.
We are not Anchorage junkyard!

No No No to Central Monofill

Thank you

DEVELOPMENT SERVICES DIVISION STAFF REPORT

File Number:	176020140001
Applicant:	Central Monofill Services, Inc.
Property Owner:	Central Monofill Services, Inc.
Request:	Planning Commission Resolution 14-33 Request for a conditional use permit in accordance with MSB 17.60 – Conditional Uses
Location:	17N02E18C010 (2840 S. Glenn Highway) and 17N02E19B006 (2560 S. Glenn Highway); within Township 17 North, Range 2 East, Sections 18 and 19, Seward Meridian
Size of Property:	118.9 acres
Public Hearing:	December 1, 2014
Planning Commission Action:	The planning commission shall conduct a public hearing and render a decision within 30 days from the close of the public hearing on the application for a conditional use permit
Reviewed By:	Eileen Probasco, Planning & Land Use Director Alex Strawn, Development Services Manager
Staff:	Susan Lee, Planner II
Staff Recommendation:	Approval, with conditions

EXECUTIVE SUMMARY

Central Monofill Services (CMS) has submitted a conditional use permit application under the requirements of MSB 17.60, for the operation of a monofill for the disposal of inert material. MSB 17.60.030(A)(1) requires a conditional use permit for the operation of junkyards and refuse areas. A "junkyard/refuse area" is defined as "a location which is commercially used for the

purpose of the outdoor storage, handling, dismantling, and wrecking, keeping or sale of used, discarded, wrecked or abandoned airplanes, vehicles, boats, building and building materials, machinery, equipment, or parts thereof, including but not limited to, scrap metals, wood, lumber, plastic, fiber, or other tangible materials". The applicant has stated that the inert debris will primarily be non-hazardous shredded residual nonrecyclable waste material from construction and demolition waste. Regulated Asbestos Containing Material (RACM) and Non-RACM will also be accepted at the site. In addition to the monofill, there will be a salvageable/recyclable materials storage yard on the site.

PROJECT DESCRIPTION

For clarification Central Monofill Services (CMS) owns the proposed monofill site properties and holds the permits for the properties; Central Recycling Services (CRS) owns and operates the recycle facilities and holds the operations contract with CMS to run the monofills; and Central Environmental, Inc. (CEI) is the demolition and abatement company and is a customer of CRS.

Please refer to the application material for the applicant's detailed project description.

Central Monofill Services (CMS) has submitted an application for a conditional use permit for the operation of an unlined monofill for the disposal of inert waste, RACM and Non-RACM. Under Alaska Administrative Code 18 AAC 60.990(64) "Inert waste" means solid waste that has a low potential to pollute air or water, and that does not normally attract wildlife; "inert waste" includes coal power plant ash, scrap metal, auto fluff, construction and demolition waste, and pavement rubble; "inert waste" does not include asphalt material that contains asbestos. The definition of "inert waste" does not include materials that contain asbestos.

Materials such as doors, windows, wood, bricks, glass, steel culvert pipe, and broken concrete that has been removed from the waste stream will be available for resale at the site. These materials will be stored at a separate area on the site from the monofill.

The two subject properties are a total of 118 acres in size. There is one single access to the site from the Glenn Highway. There are three industrial ponds located on the northern half of the property which cover 66 acres. The monofill footprint is not adjacent to these ponds. Of the remaining 52 acres, the monofill footprint is proposed to be 35.5 acres with 16.5 acres used for recycling operations. The conditional use permit is needed for 52 acres of the property. A scale house, maintenance shop and other support facilities will be needed to support the monofill and recycling operations and will be placed outside the 35.5 acre monofill footprint. The placement of material into the monofill is proposed to be over approximately 30 years.

Due to the previous earth material extraction activities on this property, the topography is essentially a large bowl. Waste materials to be deposited in the monofill will be placed to fill the natural and manmade topography of the property. The tire bales will be used as structural berms and act as visual buffers by framing the sides of the cells to contain the debris. The sides of the cells are constructed prior to filling each cell, which creates barriers on two or three sides, helping to block the wind and contain the material. A total of ten cells will be constructed over the life of the monofill.

ADEC permit regulations require that the bottom of the monofill cells be located a minimum of ten feet above the established groundwater levels. Alaska Administrative Code 18 AAC 60.990

defines "groundwater" as "water below the land surface in the zone of saturation". The ADEC requires that the separation requirement for the bottom layer of the cells be established using groundwater elevation information before materials are placed in the monofill. The elevation of the bottom layer of the waste disposal cells will be established using historical groundwater information. This information was measured over four seasons to determine the seasonal high groundwater elevation. The bottom cell will be located a minimum of 10 feet above the established seasonal high water level.

Filling of the cells will start at the southernmost part of the property and advance to the north. Each cell is proposed to be about 125 feet wide. There will be sub-cells created within the cells. As the cells increase in height the sides will be built up with tire bales that will be covered with topsoil and seeded for revegetation. These cells will be wide enough to allow equipment to maneuver and place loads in correct locations. Material will be spread into two-foot lifts and compacted. This process will continue until the layers of the cell each reach a depth of 15 feet. The working face receiving the inert materials will comprise, at any one time, an area approximately measuring 120' x 50'. The working face is the area within a cell where active filling is taking place and heavy equipment is compacting and covering the refuse. The maximum square footage that will be exposed and not covered at any one time during the monofill operation will be 25,000 square feet.

There will be two waste streams entering the facility. One stream is the material hauled from a Central Recycling Services (CRS) operation that has already been inspected and processed. The second waste stream is material hauled from known customers that has not yet been inspected. The general public will not be allowed to drop off or dispose of material at the monofill. Materials that have not been previously inspected are initially dumped on an impermeable inspection pad where they are inspected, recyclable material is removed and remaining non-recyclable material placed in the active monofill cell. The applicant states that if prohibited materials are found they will be removed for proper disposal and any contaminants will be cleaned up. The application material states that the following material will not be accepted at this monofill:

- PCBs or other Hazardous Wastes
- Household Waste
- Putrescible Waste
- Liquids
- Compressed Gas Cylinders
- Batteries
- Appliances with CFC/HCFC
- Animal Carcasses
- Petroleum Contaminated Materials

After materials have been deposited in the cell, the materials will be spread and compacted. The waste material will be shredded to a size of 12 inches or smaller. The shredded/compacted debris will be covered with daily cover which is screened fines of material three inches or smaller. The debris will be covered with soil weekly. That process will continue until the layers within the cell reach 15 feet in depth. Material excavated from cells that are under development will be used as the cover material for the operational cell. There will be a one foot lift of soil separation between each cell to create multiple fire barriers throughout the monofill. ADEC requires the monofill cells to be capped either weekly or when cells are full. This surface will be graded to drain in order to prevent surface ponding and reduce infiltration. All slopes will go to the industrial ponds.

Once the monofill cell is filled to final height, native soil, strippings, compost, etc., will be spread over the top and slopes of the cell for a minimum of two feet. This final surface will be graded to drain in order to prevent surface ponding and reduce infiltration. The cap for the monofill will be seeded and will allow the establishment of vegetation over the surface to occur. All drainage will flow away from the working face of the monofill and a minimum of 2% grade will be required. As the top sections of the monofill are completed to final height, 24" of native or imported soil will be spread over the top to serve as a final cap and to allow the reestablishment of vegetation on the site.

Material that contains 1% or more of asbestos is termed Asbestos-Containing Material (ACM). By definition, material that contains less than 1% asbestos is not considered ACM. There are two types of ACM:

- Regulated Asbestos-Containing Material (RACM) includes any ACM that is friable, or is likely to become friable due to the methods used for demolition, renovation, or disposal.
- Non-Regulated Asbestos-Containing Material (non-RACM) refers to ACM that is non-friable. Non-RACM waste must be handled carefully to prevent damage that could cause it to become friable. Non-RACM waste can become RACM waste if it is damaged so much that asbestos fibers may be released.

Friable: Used to describe ACM that, when dry, can be crumbled, pulverized, or reduced to powder by hand pressure.

Regulated Asbestos Containing Material (RACM) and Non-RACM will also be accepted at the site. RACM loads delivered to the monofill are packaged and sealed in leak proof containers and placed within the designated cell. These materials are not compacted by equipment to insure the integrity of the packaging. The application describes the process for Non-RACM (Regulated Asbestos Containing Materials) to be directly deposited in the monofill in the Non-RACM cell. The RACM disposal cell will be fenced and locked. Non-RACM and RACM have to be scheduled for delivery and disposal. ADEC requires all RACM waste to be covered with a minimum of six inches of soil or non-RACM by the end of the working day. (Refer to the ADEC *Asbestos Handling & Disposal* Fact Sheet).

The maximum finished elevation of the monofill will be 162 feet Above Sea Level. The adjacent Glenn Highway has an average finish elevation of 117 feet Above Sea Level, so the maximum height will be a little more than 40 feet above the Glenn Highway. The existing tree covered berm along the Glenn Highway has an average elevation of 130 feet Above Sea Level, with trees 20 feet and taller growing on top of that. The maximum depth of the monofill will be 75 feet with an average depth of 50 feet.

BACKGROUND

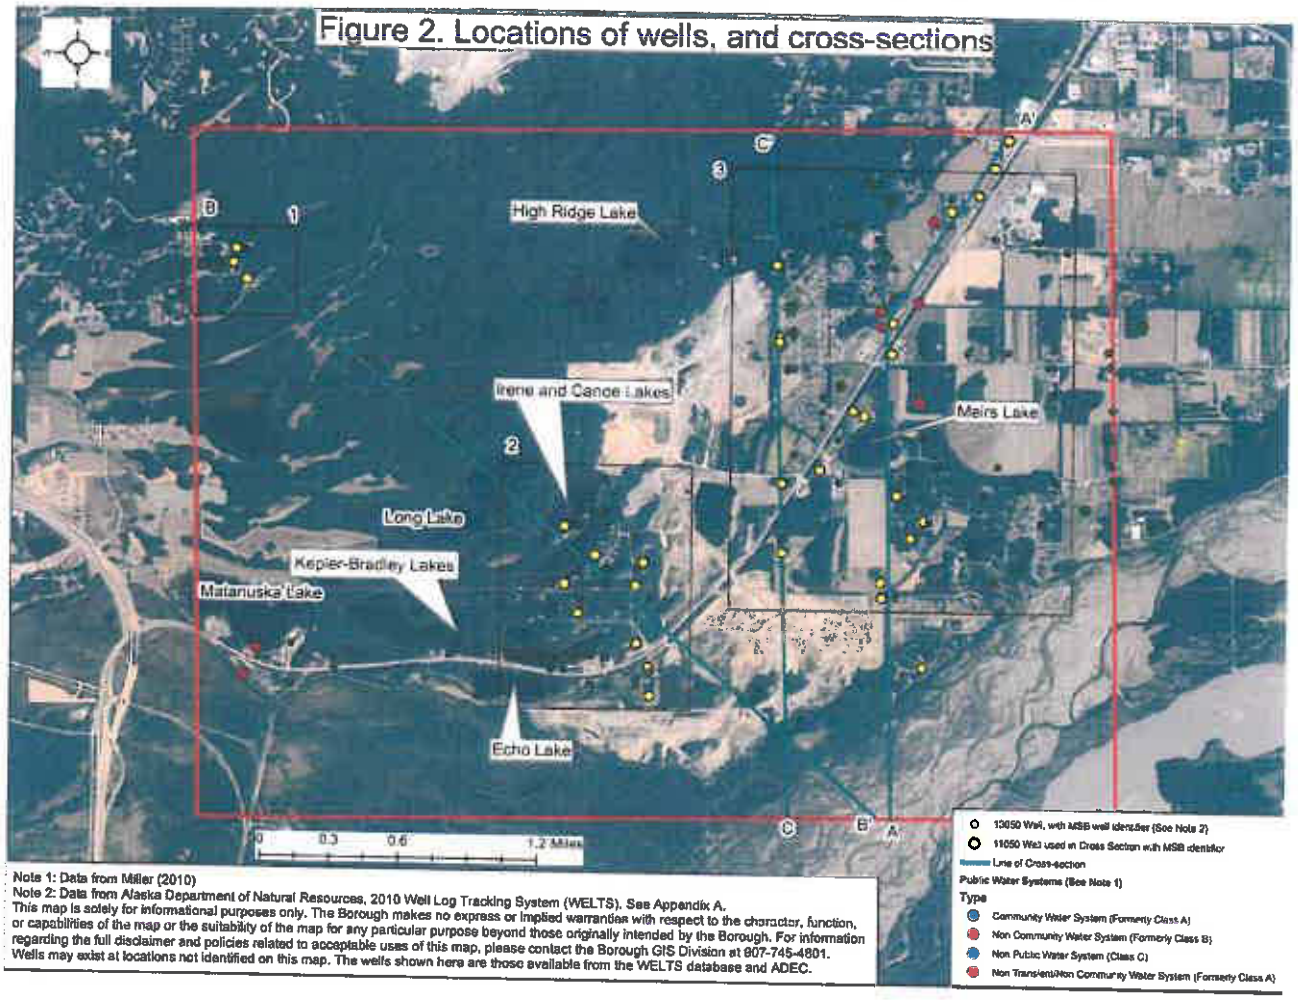
The past use of this property has been earth materials extraction. There are three manmade dredge ponds on site which are the result of previous gravel dredging. The ponds are fed from surface flow and groundwater. In 2004 there was a breach of the confining layer of the aquifer in one of the three dredge ponds that many have claimed caused problems with the local water table and lakes.

In 2010, Brailey Hydrological Consultants prepared a groundwater modeling study to assess the impact of dredging at the Anchorage Sand and Gravel Palmer gravel pit, which is directly adjacent to the north side of the proposed monofill property. In summary, this report states:

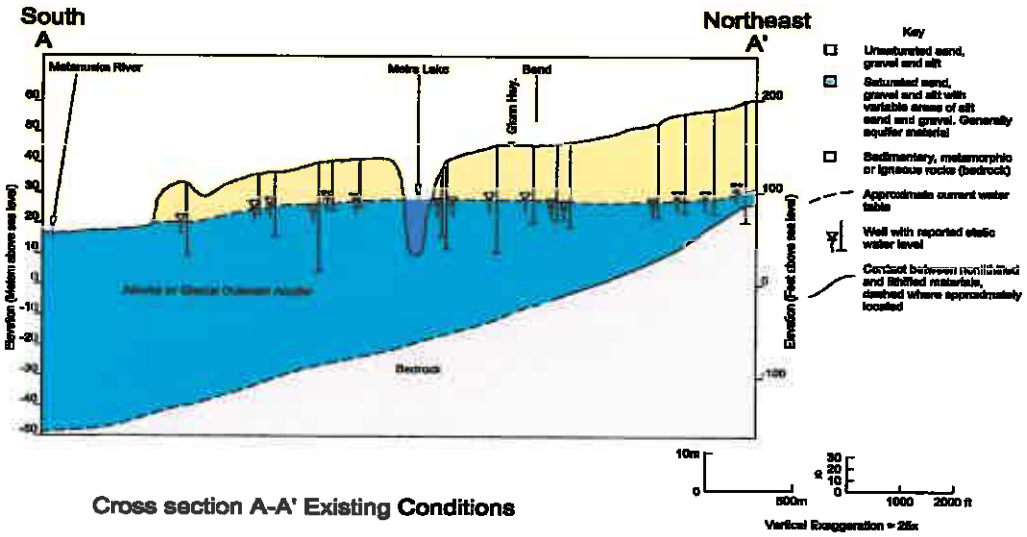
Based on a regional water table map prepared by the U.S. Geological Survey, groundwater flow is generally southward from the Talkeetna Mountain front. In the vicinity of the Palmer Pit, groundwater occurs in an unconfined aquifer tapped by numerous domestic and community water supply wells. The aquifer is relatively thick (locally over 200 feet) and commonly exhibits high well yields. Comparison of the water table elevation with adjacent floodplain elevations suggest that the unconfined aquifer is recharged by both the Matanuska River and by groundwater inflow from the north. Oxygen isotope studies performed by the U.S. Geological Survey indicate that the water table aquifer has a direct hydraulic connection to many lakes in the Palmer-Wasilla area. (Brailey Hydrologic Consultants, Groundwater Modeling Report, AS&G Palmer Pit, August 2010).

In 2010 J.A. Munter Consulting, Inc. prepared a report for the Borough on the *Potential Hydrologic Effects of Gravel Extraction South of Palmer, Alaska.* This report was prepared regarding the effects of gravel extraction in an area south of the City of Palmer (including the area of the proposed monofill site). The report addresses concerns about potential effects on nearby water wells serving individual residences and public water systems. In summary, this report states:

Several wells are located close enough to the proposed gravel mining areas that contaminants introduced into the aquifer could potentially reach the wells if the wells are located down gradient of the source of contamination. Also, capture zones of some of the wells could extend out into the gravel mining areas to draw in contaminants. With a general southward direction of flow in the study area, some nearby wells are likely to be located up gradient of the proposed mining area and would not be expected to be at risk of water quality impairments from



the proposed operations. Because a detailed and reliable water-table map for the entire area is not available, however, either for current conditions or post-mining conditions, it is difficult to evaluate groundwater flow directions in more detail. Therefore, in the absence of more detailed information, gravel extraction activities as proposed are considered to introduce a risk of impaired water quality to some existing and potential public drinking water aquifer sources.



Cross section A-A' Existing Conditions

The area of the proposed monofill is windy a substantial number of days per year. In Palmer, during the time frame of May 17, 2010 to May 17, 2011, the average maximum wind was 54 mph, the average wind was 6 mph and the minimum wind was 0 mph; the maximum wind gust was 77 mph/ average wind gust was 28 mph; and the minimum wind gust was 16 mph. During the time frame of May 17, 2011 to May 17, 2012 the maximum wind was 51 mph; the average wind was 6 mph; and the minimum wind was 0 mph; the maximum wind gust was 70 mph; the average wind gust was 26 mph; and the minimum wind gust was 16 mph. During the time frame from May 17, 2012 to May 17, 2013 the maximum wind was 48 mph; the average wind was 7 mph; and the minimum wind was 0 mph; the maximum wind gust was 69 mph; the average wind gust was 27 mph and the minimum wind gust was 18 mph. (Wind data collected from weather station at Palmer Airport).

Contaminants typically found in groundwater surrounding construction and demolition landfills include cadmium, lead, iron, manganese, several chlorinated volatile organic compounds, sulfate, hydrogen sulfide, and TDS (total Dissolved Solids). Chromium and arsenic are found if chrominated copper arsenate-treated wood is disposed in the landfill. (*Construction and Demolition Debris Landfills: Community and Occupational Health Issues*, Fall 2008, Florida Journal of Environmental Health; *Demolition Landfill Guidance*, Minnesota Pollution Control Agency, Waste/Solid Waste #5.04, August 2005; *Code of Federal Regulations, Pt. 257, App. I)*

Prior landfill studies do not take into account several factors. The type of waste in most of the studies was unknown. Some of the landfills studied started as municipal solid waste landfills or started as unlined municipal solid waste landfills before becoming inert debris landfills. Many of the landfills studied go back to a time before recycling and when little inspection or control of the waste took place. Inbound materials to the proposed monofill are proposed to be inspected and processed prior to disposal. Materials such as metals and sheet rock, that have caused

concerns for leachate production, are removed from the waste. Large quantities of sheetrock are removed from the waste and recycled by CRS.

In 2013 Central Monofill Services (CMS) submitted a conditional use permit application for the operation of an inert debris monofill at this location. On June 3, 2013 the Borough Planning Commission conducted a public hearing on this application. The conditional use permit was denied. On June 17, 2013 the Planning Commission adopted Resolution 13-30-(AM) with findings of fact and conclusions to support denial of the permit request. A copy of that resolution is included in this packet.

After the 2013 public hearing the Borough hired J.A. Munter Consulting, Inc. to prepare a hydrogeologic evaluation of the proposed monofill site. On June 27, 2013 the report was submitted to the Borough. A copy of that report is included in this packet.

The following is a brief summary of Munter's 2013 report. Munter states there appears to be no significant effort to reduce or control infiltration of rainfall and snowmelt through the waste; no provisions for an engineered native soil or other liner; with no impermeable cap, rainfall and snowmelt will infiltrate and percolate downward through the waste; water will pool up inside the waste and leachate will flow out and rain into the surrounding aquifer. The water table at this site is not well defined and the 10' separation between the bottom of the waste and the water table is insufficient. Normal seasonal variations of the water table have not been measured and reported. Potential changes in the water table have not been evaluated. There is an unreliable basis for designing the 10' water table separation at this facility. Design of this facility appears to be insufficient to assure a 10' separation from the bottom of the waste to the water table. There are no significant barriers to the migration of the leachates to groundwater and it is highly likely to result in measurable increases in contaminates beneath the facility for some distance down gradient. Groundwater is believed to flow toward the southwest and there are numerous wells in that general direction. If any significant amount of contamination should emanate from this site, it will encompass more than 20 wells within a one mile radius in a down gradient direction. Most of the known wells tap the same aquifer as the aquifer that underlies the proposed monofill site and there is the potential to contaminate water wells from this facility. This aquifer is known as an unconfined aquifer and the direction of groundwater flow in the aquifer is generally toward the south and southwest. The silt deposits above and within the aquifer are small and generally are not laterally continuous or thick enough to constitute significant protective layers on the scale of the analysis of the effects of the proposed monofill. This aquifer extends at least from Canoe Lake to the ponds northeast of the monofill and southward to the Glenn Highway and beyond and includes the proposed monofill site. The applicant needs to provide further clarification on how they would remediate the aquifer. The applicant does not appear to provide any substantive assurance that the aquifer is protected or that groundwater contamination can be detected or remediated should it occur.

On January 15, 2014 CMS submitted a new conditional use permit application for the proposed monofill. The Borough hired J.A. Munter Consulting, Inc. to review the application material. Munter submitted a report to the Borough on February 7, 2014. A copy of that report is included in this packet.

The following is a brief summary of Munter's 2014 report. Materials disposed of at inert monofill eventually rot, decay and leach into groundwater; studies have shown increased concentrations of contaminants from C & D landfills; waste breakdown will result in dissolution and entrainment of waste constituents in leachate if water flows through the waste. It is not clear

what hazardous waste will be excluded from the monofill. Only a small amount of some compounds or elements are needed to contaminate a large volume of water. It is reasonable to assume that there will be a sufficient amount of waste accumulated to generate leachate that will exceed one or more drinking water Maximum Contaminant Levels. There are no significant barriers to the migration of this leachate into groundwater and it is highly likely to result in measurable increases in contaminants beneath the facility and for some distance down gradient. The seasonal high groundwater level has not been determined at this site. The location of the guard wells will not intersect the leachate plumes. Fluctuations of water level changes should be addressed. Snow was not addressed with annual precipitation. The final cap materials for the monofill will primarily be sand and gravel, overlain with soil to support vegetative cover. These well-drained soils should not be characterized as almost impermeable, even if saturated. No data was provided on the permeability of the fill. If water enters the top of the structure, it will percolate down and eventually exit. The modeling shows that domestic drinking water wells could be contaminated from the monofill. Separation distances between the monofill and surrounding drinking water wells may be appropriate conditions. The proposed guard wells are located in places that would not detect any of the plumes shown in the groundwater modeling effort. It appears that the existing and/or proposed monitoring wells will be ineffective as detracting contaminants leaving the proposed monofill. The application material fails to present sufficient data and sound analysis to support their conclusion that the proposed monofill does not present a threat to groundwater. Insufficient data and analysis have been provided to accurately evaluate the effects of the proposed monofill.

On February 13, 2014 the Borough sent a letter to CMS requesting additional information. A copy of that letter is included in this packet. On May 14, 2014 CMS submitted a response to that request. This supplemental information is included with all of the CMS application material. CMS responded to the Munter report with reports from the following consultants: Environmental Management, Inc. (EMI), Maddox & Associates, TERRASAT, Inc., and AlaskaChem Engineering. The following are summaries from each of those reports:

Environmental Management, Inc. (EMI). The following is a summary of that report:
Larry Helgeson, P.E. responded as the engineer responsible for the design of the monofill. This monofill was designed to meet the established state and federal codes which were developed to protect both human health and the environment. It is only appropriate to evaluate this landfill against the standards that are in place to regulate inert landfills. Munter disagrees with this approach to landfill design and implies that the current standards are not appropriate for inert waste disposal but does not offer any alternative standards to use. Due to the borough's concerns about the established standards not being sufficient, CMS hired an expert in landfill design and assessment to review EMI's design for this monofill. The submitted operational procedures developed for this landfill will prevent hazardous waste, as defined by the federal government (40 CFR 261.3), from being placed in the landfill. The landfill is designed to minimize the moisture levels in the material, so that the rate of decay and rot will be very slow and will not significantly impact any leachate, if there is any leachate at all that leaves the monofill. The Synthetic Precipitation Leaching Procedure (SPLP) was used to check for potential contaminates of concern from the waste. The SPLP is an EPA approved method to test waste. The method is not designed to test water for drinking standards. It is designed to identify contaminates that may be of potential concern in waste water. This landfill has been specifically designed so that the waste will never stay in a saturated condition. CMS provided a ground water monitoring plan to verify that the monofill is not impacting the groundwater. We have found the probability of creating a leachate that will impact the groundwater is so low that that groundwater monitoring is not necessary and recommend the submitted ground water monitoring plan be

withdrawn and not implemented. Water level data from all four seasons with over 20 events from April 24, 2013 to April 15, 2014 has been obtained and provided to the borough. The applicant plans to continue collecting water data in order to continually update the data. The bottom of the monofill cells will be established based on all of the water data that is collected up to the time of construction of that cell. The seasonal high water table shown on Figure 6 (page A-8 in the application package) is based on the water data collected through April 15, 2014. This will be used for the final design for construction unless a higher water table is measured between now and the time of construction.

Maddox & Associates, Inc. The following is a summary of that report:
Maddox & Associates was hired by CMS to perform a review of the site hydrology and leachate concerns raised with the proposed monofill. The proposed monofill is located in a semi-arid climate where the balance between the annual precipitation and the annual evaporation precludes the formation of any significant volume of leachate. Any minor volumes of leachate that may be produced in the monofill will not have the ability to cause a significant impact on the underlying aquifer. CRS removes large quantities of drywall from the waste stream for recycling. This changes the waste composition from historical monofills that may have had elevated sulfate levels. No significant water will be available to percolate through the inert refuse, nor to "pond" at any level within the refuse mass. Therefore, drywall, if it were to be present in the waste stream at the proposed monofill, would not degrade and potentially impact the aquifer. The proposed monofill is taking in post recycling waste, which is waste that has been processed to remove metals, appliances, etc. for their commodity value. The material brought to CRS is sorted, screened, and processed to ensure that the material is free of hazardous waste and putrescible material and/or liquids. Every effort is made to ensure that no materials that may produce a harmful leachate will be present in the monofill. The proposed monofill will be located in an area of relatively low precipitation, with the base of the refuse a minimum of 10 feet above the seasonal high water table. The monofill will be located in a semi-arid environment, where the annual precipitation and annual evaporation are essentially equal. The average annual precipitation rate measured at the Matanuska Agriculture Experiment Station is approximately 15 inches. Under these climatic conditions, particularly when the precipitation is less than 15.75 inches per year, leachate is not formed in a landfill. Alaska State requirements are met for an inert landfill with respect to the minimum separation from the water table of 10 feet and no liner required.

ADEC requires a minimum 10' separation distance between the bottom of the refuse and the recorded historic high water table. The on-site groundwater monitoring wells were installed in April 2013. The three wells that lie under the footprint of the proposed monofill (MW#2, #3, & #4), which can be utilized to indicate the depth of water beneath the refuse, the minimum depth to water of 25.99 feet was recorded in well MW#4 was recorded January 23, 2014. The greatest depth to water recorded occurred on April 30, 2013 in MW #3 at 37.61 feet. Higher than normal precipitation occurred in the years 2011, 2012, and 2013. Based on this fact, the historical recorded site groundwater levels will be used to determine the historical high groundwater levels beneath the proposed monofill site.

One year of groundwater monitoring will be conducted in the existing on-site wells in order to collect sufficient data to determine if it will be necessary to construct down gradient guard wells. The groundwater monitoring wells were installed to determine the depth to groundwater beneath the base of the refuse in the proposed monofill in order to meet the ADEC requirement to maintain a 10-foot buffer zone between the refuse and the water table; and to collect data for modeling. Modeling results have indicated that there will be no contaminant plume extending

down gradient from the landfill mass. Therefore, it is not expected that additional down gradient wells will be required.

As working cells are completed and there is no working face, infiltration will decrease significantly. As each cell is completed and the vegetative cover established, the volume of infiltration will be significantly reduced. As vegetation is added, most precipitation will evaporate. A simple top cover with vegetation will reduce infiltration through evaporation. As the landfill expands and more cells are completed with the final vegetative cover, the volume of infiltration will be reduced. The volume of potential infiltration will be very low to begin with and will be further reduced as the landfill evolves, cell by cell.

The most vulnerable portion of the monofill at any one time is the "working face", which is the area within a cell where active filling is taking place and heavy equipment is compacting and covering the refuse. The working face of the proposed monofill will typically cover an area approximately 120' x 50'. As cells are completed and there is no working face, the potential for infiltration will decrease significantly. With the establishment of a vegetative cover as each cell is completed and the monofill expands, the volume of infiltration will be significantly reduced. The development of a vegetative cover will result in increased evaporation (evapotranspiration) and the minimal (to none) infiltration that may be present to begin with will be reduced to essentially nothing as the landfill evolves, cell by cell. Establishment of the native ground cover on the final cap of each cell would result in increased evaporation and reduced potential for infiltration.

The Munter report states that gravel mining close to the proposed monofill site could have the effect of lowering the water table several feet over an extended area. The monofill site will lie within the area of projected water table decline. If Munter is correct, the lowering of the water table would aid in maintaining the 10-foot minimum separation required for the monofill by the ADEC.

The potential for the production of leachate at the monofill site is low based on the following facts: The proposed monofill site is located in a semi-arid climate; the annual precipitation is relatively low; the annual evapotranspiration is approximately equal to the annual precipitation; the ground is frozen during a significant portion of the year; no significant period of residency of liquids within monofill materials; and no significant recharge in area of monofill.

TERRASAT, Inc. The following is a summary of that report:
TERRASAT tested Munter's assumptions about water quality exceedances and found his conclusions about water quality exceedances invalid. TERRASAT provided the calculation sheet using Munter's estimates of groundwater flow, infiltration, and opinions about sulfate, arsenic, iron and benzene to verify if his opinions are valid. The results from these calculations show that groundwater will not be significantly impacted. The results of TERRASAT's calculations show that the contamination issues raised by Munter are not based on fact or sound science.

TERRASAT evaluated infiltration processes and potential leachate fate and transport through the proposed monofill. They extended the leachate model to include groundwater migration to the property boundary, 50 feet down gradient of the proposed monofill. Three models were presented to describe the physical infiltration processes. Two potential contaminants of concern were identified, one being sulfate and the other is manganese. The results predict the likelihood that analytes will comply with ADEC's drinking water standards.

Seven monitoring wells were previously installed at this site. Groundwater levels were measured in July 2013 and at other times during the last 12 months. The water table generally fluctuates less than one foot. The unconfined aquifer that underlies the proposed monofill consists of sand and gravel with a relatively high hydraulic conductivity. Water is supplied to this aquifer primarily by infiltration from the Matanuska River.

The Palmer Alaska Experiment Station data from 1982 through 2012 reports an average annual total precipitation of 15.94 inches and a yearly total of evaporation of 18.34 inches. These measurements suggest that infiltration is -2.4 inches per year. In other words, soil infiltration does not occur. The Palmer Job Corp precipitation data from 1993 to 1997 and 2004 to 2012 reports that the average precipitation for this period is 15.63 inches per year. The measured evaporation rates for 1993 to 1997 was 15.57 inches, which suggests soil infiltration could be 0.06 inches per year. In summary, existing records suggest infiltration is minimal or non-existent.

The monofill cover is designed with an 18" thick silt cap that is overlain with a 6 inches of topsoil and planted with grass. The first process that occurs during a rainfall event is the vegetation incepts some or all of the rainfall. Rainfall in excess of inception reaches the soil and begins to infiltrate.

Three models were evaluated to explain the physical processes of water infiltration into the proposed monofill. The conceptual model shows the configuration of the monofill, the parameters that control infiltration and the infiltration pathways. The existing climatic records show infiltration is unlikely to occur. If some infiltration occurs, the amount will be minor. Vegetation inception prevents some rain from infiltrating the first layer of top soil.

Results from the Green-Amp model show infiltration is a slow process in both the top soil and the silt cap. Many storms without evaporation are required to infiltrate small amounts of water into the ground. Some of the infiltrated water is evaporated, some is stored as matric water for later plant use, and some comes back to the top boil by capillary pressures. For any water that migrates below the silt cap, the water will move through a residual waste cell in hours, as an unsaturated flow. This means little time is available to form leachate.

ADEC's leachate screening model shows that analytes, above detection limits from leachate studies, will be in compliance with ADEC drinking water standards. The leaching testing procedure requires water saturation, the addition of acid, and agitation to generate leachate. Those processes are absent in an unsaturated monofill.

Physical processes, such as cation fixation, sorption, and biodegradation will further reduce risks of leachate migration. The proposed monofill appears to be protective of groundwater sources if the monofill is constructed as modeled in the conceptual model.

AlaskaChem Engineering. The following is a summary of that report:
Ralph Hulbert, P.E. investigated the infiltration, percolation, and groundwater recharge near Palmer. That study examines the relationship between precipitation and groundwater recharge in the area south and west of Palmer pertinent to the proposed monofill.

Based on these investigations the proposed monofill will not cause recognized adverse health impacts from contamination of groundwater. There appears to be robust groundwater at the site

primarily supplied from the Matanuska River and the Talkeetna Mountain foothills. The estimated 1.4 inches per year recharge from precipitation in this area is a minor contribution.

Mr. Hulbert's study on infiltration, percolation, and groundwater recharge near Palmer states the following: *"A borough sponsored regional groundwater study, prepared by J. Jokela, James Munter, and James Evans in 1991, used surface water body elevations and well drillers' logs to plot groundwater contours. There was no fieldwork or apparent attempt to check if the wells tapped the same aquifer. This study grouped the Palmer terrace with the Lazy Mt., presuming the source of groundwater at both locations is local precipitation. Flow directions were drawn toward the Matanuska R., southeast in the southern Palmer terrace (as marked on Figure 1), ignoring Trainer's observations. This mistake is far more than missing a local groundwater flow direction by 90 degrees; this area has very productive wells for irrigation and city supply, and identifying its groundwater source is critical. If groundwater flows southeast, its source must be extremely high local precipitation recharge absent in adjacent areas), while a southwest flow with the Matanuska R. as the source explains the abundance".*

Summary
The borough has reviewed the information provided by J.A. Munter Consulting, Inc., Environmental Management, Inc., Maddox & Associates, Inc., TERRASAT, Inc., and AlaskaChem Engineering. The consultants hired by CMS have provided documentation to substantiate their conclusions. This information and documentation provided further clarification of the monofill operation. Modeling and calculations have been provided to disprove that large quantities of contaminated leachate will develop from the monofill and flow off-site. With the combination of limited annual precipitation, seasonally frozen ground, evapotranspiration effects, run-off of precipitation and numerous other factors discussed in the monofill analysis, there is very little transmission of water through the monofill, thus not creating the quantities of leachate Munter suggests. The consultant's reports show that if minor amounts of leachate are generated it is not expected to contain harmful concentrations of contaminants.

LAND USE

Existing Land Use:
This property was previously used for earth materials extraction. There are pre-existing legal nonconforming use rights for earth materials extraction for this property. Pre-existing legal nonconforming status for material extraction means the industrial use was in existence prior to the current regulatory structure and was not evaluated for compatibility with surrounding land uses.

Surrounding Land Uses:
Surrounding land uses include earth material extraction sites to the north and on the south side of the Glenn Highway; residential subdivisions to the west and northeast; and agricultural uses to the east of the site.

COMPREHENSIVE PLANS

The proposed monofill site lies within the Borough-Wide Comprehensive Plan (2005 Update) boundary. Some of the goals and policies that apply to this project are as follows:

Land Use Goals and Policies:
Goal (LU-1): *Protect and enhance the public safety, health, and welfare of Borough residents.*

Policy LU1-1: Provide for consistent, compatible, effective, and efficient development within the Borough.

Goal (LU-2) *Protect residential neighborhoods and associated property values.*

Policy LU2-1: Develop and implement regulations that protect residential development by separating incompatible uses, while encouraging uses that support such residential uses including office, commercial and other mixed-use developments that are shown to have positive cumulative impacts to the neighborhood.

Goal (LU-3): *Encourage commercial and industrial development that is compatible with residential development and local community desires.*

Policy LU3-1: Develop and implement regulations that provide for non-residential development.

Goal (LU-4): *Protect and enhance the Borough's natural resources including watersheds, groundwater supplies and air quality.*

Policy LU4-1: Identify, monitor, protect, and enhance the quantity and quality of the Borough's watersheds, groundwater aquifers, and clean air resources.

This site is also located within the boundary of the Core Area Comprehensive Plan (2007 Update) boundary. Some of the goals and policies that apply to this project are as follows:

Land Use Goals and Policies

Policy 1-B: *Promote an orderly land use pattern suited to the demand for attractive settings in which to live, work, shop, learn, play, and carry on other daily activities.*

Policy Discussion: As the Core Area's population grows – it is forecast to double by 2025 and absorb most of the remaining vacant land in the Core Area – the limited vacant land supply must provide a balanced supply of well-located sites for homes, businesses, private and public institutions, industry, parks and recreation, public improvements, and other purposes. The plan needs to provide a place for every permitted land use, but not all land uses go well side-by-side. Some uses such as residences and open space or retail trade and service business are usually compatible and enhance each other. Others, like heavy industrial activities and residential subdivisions, make poor neighbors and are best separated by distance or buffers.

Policy 1-J: *Encourage light industrial parks*

Policy Discussion: The Core Area does not have and is not expected to attract much heavy industry, not including earth materials extraction sites. However, the Core Area already has pockets of light industrial uses such as outdoor storage, construction yards and shops, building materials supply, garage and outdoor vehicle storage yards, warehousing, utility buildings, miscellaneous outdoor storage, etc. These industrial uses are necessary and a good fit for the local economy, with good growth potential. Demand for sites for industrial uses will increase as the Core Area's economy matures. Even so, industry will remain a modest land use in the overall picture.

These light industrial uses are generally mutually compatible. They tend to have similar locational requirements, such as good highway access and public utilities, and separation from residential neighborhoods, schools and recreation facilities, and public institutions. Designating sufficient well-situated tracts for light industry will help create a more attractive climate for these activities by enabling them to operate efficiently and with minimal conflict with other uses.

Restored earth materials extraction site with good highway access can be prime candidates for light industrial uses.

Policy 1-M: Collaborate with operators of large earth materials extraction sites to plan for site reclamation and re-use after earth materials extraction activities are finished.

Policy Discussion: Earth materials extraction sites – gravel and sand pits – are an extensive active interim land use in the Core Area. Several former sites have been redeveloped or await redevelopment. Earth materials extraction is expected to continue as a local industry, with additional sites being put to that interim use in the future.

Rising land values will enhance the development potential of former sites which often become prime real estate for new uses. Redevelopment of these sites makes good use of the borough's land base and enhances the value and economic potential of nearby properties.

This policy proposes that the borough work jointly with property owners, consistent with borough ordinances, to plan for redevelopment of these sites for productive and profitable reuse. The borough can facilitate redevelopment by ensuring that earth materials extraction is managed in a manner that conserves future redevelopment options and by providing essential public infrastructure for redevelopment.

Goal 7. Environment: *Protect and conserve the natural resources that support the well-being of residents and the region's tourism and recreation economy.*

Policy 7-A: *Protect groundwater supplies and quality.*

Policy Discussion: Many existing and future residences and businesses will depend on on-site groundwater resources for their water supply. Protection of the supply and quality of groundwater is vital to sustain this arrangement.

Policy 7-B: *Protect surface water quality.*

Policy Discussion: The Core Area's many lakes are valuable natural and economic assets. They provide an attractive setting for residential development, enhance property values, support a variety of public and private recreational activities, and provide natural habitat, absorb runoff. These lakes are linked to streams and wetlands with similar positive values. The borough's existing program of lake management plans already provides some protection for surface water quality.

The Core Area Land Use Map has designated this area as *"Potential Earth Materials Extraction Redevelopment Sites"*. The comprehensive plan states "this category includes current or former earth materials extraction sites of 20+ acres. The borough code treats materials extraction sites as interim uses. These sites are prime candidates for eventual redevelopment for residential, commercial, industrial, or institutional uses. Mixed-use development may also be appropriate, depending on site location and characteristics".

Applicant's Comprehensive Plan Review

CMS reviewed the Matanuska-Susitna Borough Comprehensive Plan (2005 Update) and Matanuska-Susitna Borough Core Area Comprehensive Plan (2007 Update). These plans manage land use to limit residential and commercial sprawl, limit proximity of incompatible land uses, and to encourage uses that support one another. The selected site has been an industrial material extraction site and our proposed new operation is industrial in nature. This CUP

application and CMS's proposed operation does not change the land use of the property. If the type of land use has not changed, the CUP would not create any compatibility issues. Residential, recreational or agricultural property is not being changed to industrial. Industrial property is staying industrial. Low Density residential property makes up less than 25% of the surrounding properties.

Many Goals of the comprehensive plans are to protect natural resources, develop green space and preserve agricultural land. These goals can be met with approval of this CUP. This CUP will not change the type of land use in the interim and as the monofill is completed, green space or agricultural land will be created on the top of the fill. Creation of this green space or agriculture land meets goals of the comprehensive plans. Many other developments could be proposed for this property that would required no MSB permitting, and not protect natural resources. The Recycle Facility and Monofill can be developed with proper engineering and operational controls to protect natural resources and public health. Two other C&D Monofill's have operated within 2 miles of the subject site for over 10 years with no known adverse impact to public safety, health, or natural resources. These other monofill accept C&D waste but do not perform the recycling, sorting or processing of the waste that leads to the waste diversion. This additional processing also insures any hazardous or prohibited items are removed prior to disposal.

CMS identified the following goals and policies in the Core Are Comprehensive Plan (2007 Update) that are applicable to this project:

Policy 1-J: Encourage light industrial parks

Policy 1-M: collaborate with operator's of large earth materials extraction sites to plan for site reclamation and re-use after earth materials extraction activities are finished.

Staff Response
With conditions, the operation of the proposed monofill at this location will be consistent with the goals and policies of the Borough-Wide Comprehensive Plan (2005 Update) and the Core Area Comprehensive Plan (2007 Update). The previous use of this site was for earth materials extraction. There are pre-existing legal nonconforming use rights for earth materials extraction for this property, which means that the industrial use was not approved under the current regulatory structure or evaluated for compatibility with surrounding land uses. The surrounding land uses include earth material extraction sites to the north and on the south side of the Glenn Highway; residential subdivisions to the west and northeast; and agricultural uses to the east of the site. After the monofill is completed the site can be developed for different uses in the future.

The proposed monofill is an industrial use. The site can be screened from the rights-of-way and adjacent residential properties. Conditions can be set to prevent material from blowing off-site. Documentation has been provided demonstrating that the monofill operation does not have the potential for groundwater contamination that could have negative effects on drinking water and surface water quality. The monofill can be developed with proper engineering and operational controls to protect the natural resources and public health and safety.

REVIEW OF APPLICABLE CRITERIA AND FINDINGS

MSB 17.03: Public Notification

Finding: Notices were mailed to all property owners within one-half mile of the site. There were 205 notices mailed. Over 150 written comments were submitted. The public hearing notices were published in the October 17, 2014 Frontiersman. The application material was also posted on the Borough web site. The property is not located within a community council boundary; however, the Gateway Community Council was notified of this permit request. The Gateway Community Council submitted a resolution opposing this request.

MSB 17.60: Conditional Uses

Section 17.60.100 General Standards.

(A) A conditional use may be approved only if it meets the requirements of this section in addition to any other standards required by this chapter.

(B) In granting a conditional use permit, the planning commission must make the following findings:

(1) The conditional use will preserve or not detract from the value, character, and integrity of the surrounding area.

APPLICANT'S STATEMENT

The following is the applicant's response to 17.60.100(B)(1) and 17.60.100(B)(2).

The proposed Conditional Use is compatible with the surrounding uses. The existing use of the site is for Earth Materials Extraction, an Industrial use. Large scale gravel extraction operations or commercial operations account for 76% of the surrounding properties. Low density residential only accounts for 24% of the remaining surrounding properties.

Recycle facility component of the CUP is a light industrial use that would be buffered by the Monofill. The use of old gravel pits for industrial use is supported by the comprehensive plans. Granting of this CUP will allow filling and reclamation of areas of the old gravel pit turning them into green space that could be used for parks or agriculture.

The proposed Conditional Use will not be harmful to the public health, safety, convenience or welfare. The inspection, handling and processing of the materials insures that regulatory restricted materials are not delivered or disposed of at the proposed facility. Only ADEC approved "inert waste" will be allowed for disposal at this facility. Recycling and processing of the waste such as the CRS recycle facility in Anchorage removes other materials that could cause odors. Odors related to neighboring farming operations such as land application of manure and fertilizers create more odors than will ever emanate from this facility.

Operations at the facility will be screened from view as required by code. The existing topography will screen most operations. The existing mineral extraction use requires the same screening needed for a Junk Yard CUP. As areas of the site are filled above the existing topography the required cell construction will create additional screening. Cells of no greater than 15' high will be built to contain the waste materials. These cells have soil covered earthen berms around the perimeter to contain the waste and additional provide the required screening. See the Attached drawings.

Best Management Practices to include: not unloading debris during high wind events, regular/timely compaction with a sheep's foot compactor, weekly covering of waste with soil, construction of 15' tall cell berms and the use of portable catch fences reduce the likelihood of any windblown debris from leaving the site. Employees will regularly patrol the perimeter of the property to clean up any loose debris if any.

Noise from the site will not exceed current Borough Code and will be similar or less than what is currently allowed or heard from the existing earth materials extraction operations.

Traffic to and from the site will not exceed current Borough Code. Traffic will enter the site from the Glenn highway and will not create any issues of mixing commercial traffic with residential.

According to the attached Maddox & Associates report the Monofill can be constructed and operated without an impact to groundwater.

If the site is not visible to the public, nothing blows off site, no odors emanate from the property, does not exceed code requirements for sound and does not pollute the ground water then the requirements of 17.60.1 and 2 are met.

Monofill design and operations are permitted by the Alaska Department of Environmental Conservation (ADEC). Again, the ADEC permit requirements protect public health, safety and welfare. The proposed monofill design has been submitted to ADEC for review and approval. ADEC has approved the proposed monofill design pending receipt of the MSB CUP. The proposed uses will not increase activities beyond what the property is already permitted for, and therefore, will not negatively impact the public and/or their convenience.

As this property is private property, signage will be posted at all entrances to the property including the maintenance of the property on Lot C010 informing the public to take caution of not entering the site unless authorized and/or accompanied by authorized personnel. This access point will prevent unsolicited visitors to trespass onsite (pedestrians/target practice/off-road vehicle usage) and away from any site activities.

There is also no concern of wildlife, or domestic animals, being attracted to the inert debris and the monofill operations. Since there will be no putrescible waste allowed (or disposed of) in the monofill, there will be no animals attracted to the site. The lack of putrescible waste eliminates odors and/or disease issues on or off site.

The recent renewal of the Alaska Demolition CUP for the Rebarchek Pit is further evidence a C&D Monofill in the MSB can be operated safely within the requirements of 17.60. During the public testimony for this CUP only one person testified. The testimony said although things had operated well they had issues with odors from the site and thought the weeds on the perimeter berm were unsightly. Nobody testified or made complaint about property values, incompatibilities, noise debris or other issues. The CMS Monofill will not have the same odor issues as the AK Demolition Monofill as materials are inspected processed and handled differently to remove the offending materials prior to delivery to the CMS site. If after 10 years of operation the AK Demolition Monofill only had one person speak a the Public Hearing it is a fair assumption the CMS Monofill can be operated as well or better. The CMS operation has more extensive testing, inspection, processing, handling and monitoring than either of the other two C&D Monofill's located within 2 miles of the subject site.

It should be found that the CMS CUP can meet the requirements of 17.60,

STAFF FINDINGS

Finding: In 2013, Borough staff documented trash and daily cover (screened fines) that had blown from the monofill site onto adjacent properties.

Finding: ADEC regulations (18 AAC 60.420(2)) state a monofill must be operated so that litter is controlled by fencing or another approved means, and is removed from access roadways and other areas in the facility.

Finding: This region experiences frequent multiple-day high-wind events each year since it is at the confluence of the Matanuska and Knik River valleys. Loose debris and dust from the fill has, and is, expected to continue to scatter beyond the boundaries of the site.

Discussion: On October 27, 2014 borough staff conducted a site visit at the Birchwood Landfill, where Central Recycling Services (CRS) is depositing the same type of material that is proposed to be deposited in this monofill. Staff observed loose plastic materials and pieces of Styrofoam in the landfill that could easily become airborne. Some of these materials were still loose even after being compacted. Staff did not observe any windblown trash on the adjacent property. However, it should be noted that the wind data for the Birchwood Airport indicates that the average wind speed is about half of what the wind speed is at the Palmer Airport.

Finding: The 15' tall cell berms will be constructed prior to waste placement.

Finding: As the cells increase in height the sides will be built up with tire bales that will be covered with topsoil and seeded for revegetation.

Finding: The use of a large sheep's foot landfill compactor to place and immediately compact the waste in the cell is the next method to prevent loose and blowing debris.

Finding: Regularly covering the waste with soil further prevents blowing debris.

Finding: The daily cover/screened fines consist of shredded materials that are less than three inches in size. Material this size is easily distributed by the wind.

Finding: The inert debris that will be deposited on the site will be shredded into pieces 12 inches or smaller. Material this size can also become windblown.

Finding: After the residual material is deposited and compacted it will be covered with the daily cover/screened fines, which will also be compacted. The monofill material will be covered with soil weekly.

Finding: The applicant has stated that a remote weather station will be placed on the site to monitor wind and when sustained wind conditions on the site exceed 20 mph, waste will not be unloaded without secondary containment in place.

Finding: Secondary containment proposed by the applicant involves the use of portable catch fences up to 15' tall and of variable lengths. The catch fences are used to slow the wind down and catch blown debris downwind.

Finding: The normal size of opening on the catch fences is 2" x 2".

Finding: The openings on the catch fences are still large enough that smaller pieces of material could still blow through them.

Discussion: In order to prevent material from blowing off-site during wind events staff is recommending the following measures: material not be deposited on the site when sustained winds exceed 10 mph; the stockpiled daily cover either be contained within a covered trailer or completely covered with tarps that are secured to ensure that material does not become airborne; the monofill material be covered with soil, secured tarps, or other appropriate measures, more frequently than weekly during wind events; catch fences installed downwind of active monofill cells, with fencing mesh size a maximum of one inch (1") in size; and CMS staff to monitor the site daily for windblown material.

Finding: The previous use of this site was for earth materials extraction. There are pre-existing legal nonconforming use rights for earth materials extraction for this property, which means that the industrial use was not approved under the current regulatory structure or evaluated for compatibility with surrounding land uses.

Finding: The surrounding land uses include earth material extraction sites to the north and on the south side of the Glenn Highway; residential subdivisions to the west and northeast; and agricultural uses to the east of the site.

Finding: The site is required to be visually screened on a year round basis from the view of any traveled or public right-of-way. The site must be screened from the Glenn Highway and from the section line easement on the west side of the property and the east-west section line running through the middle of the property. Staff is recommending the site also be screened from the residential properties on the west side.

Finding: The proposed monofill is an industrial use. The monofill can be screened with existing berms and by building up the berms and constructing site obscuring fencing. Screening from the western properties will have to be developed as the site is built up.

Finding: Salvageable/recyclable materials that are stored outside must also be screened from the Glenn Highway and section line easements on the property.

Finding: The maximum finished elevation of the monofill will be 162 feet Above Sea Level. The adjacent Glenn Highway has an average finish elevation of 117 feet Above Sea Level, so the maximum height will be a little more than 40 feet above the Glenn Highway. The existing tree covered berm along the highway has an average elevation of 130 feet Above Sea Level. The finished revegetated height of the monofill will be above the berm on the south side, adjacent to the Glenn Highway.

Discussion: The State of Alaska Department of Transportation and Public Facilities have plans for construction of the Glenn Highway, milepost 34 – 42 to accommodate increasing traffic. This application is located at approximately milepost 38.4 of the Glenn Highway.

The State of Alaska Department of Transportation and Public Facilities Glenn Highway schedule for reconstruction of the Glenn Highway milepost 34 – 42 is:

2008 – 2011 Environmental Document Re-Evaluation
2011 – 2015 Project Design
2012 – 2015 Right-of-Way Acquisition
2016 Construction Begins (Dependent upon future funding)

The applicant is aware that this highway project may condemn some of the CMS property including part of the existing berm. If that occurs, CMS will be required to install and maintain fencing or an earthen berm in order to comply with MSB 17.60.110. In addition, if this project may require the driveway to the CMS property to be moved .

Finding: Should the operation be modified as a result of the highway project, an updated site plan and plan of operations will need to be submitted to the Borough.

Finding: The previous use of this site was for earth materials extraction.

Finding: The surrounding land uses include earth material extraction sites to the north and on the south side of the Glenn Highway; residential subdivisions to the west and northeast; and agricultural uses to the east of the site.

Finding: The proposed monofill is an industrial use.

Finding: The site can be screened from the rights-of-way and adjacent residential properties.

Finding: Conditions can be set to prevent material from blowing off-site.

Finding: Documentation has been provided demonstrating that the monofill operation does not have the potential for groundwater contamination that could have negative effects on drinking water and surface water quality.

Finding: The monofill can be developed with proper engineering and operational controls to protect the natural resources and public health and safety.

Conclusion of Law: With conditions, the proposed monofill is consistent with the goals and policies of the Borough-Wide Comprehensive Plan (2005 Update) and the Core Area Comprehensive Plan (2007 Update)

Conclusion of Law: Based on the above findings, the proposed monofill will preserve and will not detract from the value, character, and integrity of the surrounding area as the monofill will be screened from the Glenn Highway, the section line easements and residential properties to the west. Conditions will be set to address trash and debris containment on the site. Documentation has been provided showing that the proposed monofill will not contaminate the groundwater or have negative effects on drinking water or surface water quality (17.60.100(B)(1)).

(2) That granting the conditional use permit will not be harmful to the public health, safety, convenience, and welfare.

APPLICANT'S STATEMENT
Refer to the above applicant statement.

STAFF FINDINGS
Finding: Comments received regarding the proposed monofill raised the following concerns:

- Dumping of material without MSB or ADEC permits
- Dumping of hazardous waste
- Trash in the water
- Water pollution
- Health problems
- Pollution of surrounding lakes
- Protection of watershed and aquifer
- Compromising the aquifer
- Windblown unhealthy dust and particulates from the monofill
- Contamination of water wells
- Windblown materials/debris onto surrounding properties
- Previous problems with gravel extraction on this property and rising water table
- Breaching of berm between two of the manmade lakes and impact on surrounding water levels
- Lack of oversight and planning
- Applicants disregard for regulations
- Lack of CMS's ability to manage and provide oversight of the facility
- Concerns about reclamation of the property
- Contamination of soil
- Lowering of property values
- The Glenn Highway is a Scenic Byway
- Threat to migratory and breeding birds
- How the redesign of the Glenn Highway will affect this site
- Rising water levels of nearby lakes
- Improper handling and disposal of asbestos
- Concerns about lead based paint, mercury and heavy metals deposited in the monofill
- Too close to residential area
- Contamination of fish in Canoc, Kepler-Bradley Lake system
- Inconsistent with comprehensive plans
- Highway safety and access issues

Finding: There have been many concerns and comments regarding the potential for groundwater contamination that could have negative effects on drinking water and surface water quality. The applicant has provided the following documentation from four consultants indicating that this will not be the case:

- Groundwater data has been collected.

- Based on the groundwater data the monofill will be designed to be at least 10 feet above groundwater.
- Water level data is continually being collected.
- The water table generally fluctuates less than one foot.
- The water that supplies the unconfined aquifer that underlies the proposed monofill is primarily through infiltration from the Matanuska River.
- The bottom of the monofill cells will be established based on all of the water data that is collected up to the time of construction of that cell.
- On-site groundwater monitoring wells were installed. Three wells lie under the footprint of the proposed monofill, which can be utilized to indicate the depth of water beneath the refuse.
- Historical groundwater levels will be used to determine the historical high groundwater levels beneath the proposed monofill site.
- If there is any leachate at all, the monofill is designed to minimize the moisture levels in the material, so that the rate of decay and rot will not significantly impact any leachate that leaves the monofill.
- The monofill is designed so that waste will not stay in a saturated condition.
- CMS submitted a groundwater monitoring plan with their application. Subsequently CMS withdrew the plan after their consultant EMI found that the probability of creating a leachate that would impact the groundwater is so low.
- The proposed monofill is located in a semi-arid climate where the balance between the annual precipitation and the annual evaporation precludes the formation of any significant volume of leachate. The average annual precipitation rate in the area of the proposed monofill is approximately 15 inches. Under these climatic conditions, particularly when the precipitation is less than 15.75 inches per year, leachate is not formed in a landfill.
- Material brought to the facility is sorted, screened and processed to ensure that the material is free of hazardous waste and putrescible material and/or liquids.
- CRS removes large quantities of drywall from the waste stream for recycling.
- No significant water will be available to percolate through the inert waste, nor to "pond" at any level within the refuse mass.
- ADEC requirements are met for an inert landfill with respect to the 10' minimum separation distance between the bottom of the refuse and the recorded historic high water table and no liner required.
- Testing for potential contaminants from the waste has occurred. EMI tested the residual material using the Synthetic Precipitation Leaching Procedure (SPLP) to check for potential contaminants of concern from the waste. This method is not used to test water for drinking water standards. It is designed to identify contaminants that may be of potential concern in waste water.
- Modeling results have indicated that there will be no contaminant plume extending down gradient from the landfill mass.
- Leachate modeling identified two potential contaminants of concern: sulfate and manganese. The results predict that the analytes will likely comply with ADEC's drinking water standards.
- The development of a vegetative cover will result in increased evaporation (evapotranspiration) and the minimal infiltration will be reduced as the landfill evolves, cell by cell.

- Establishment of the native ground cover on the final cap of each cell will result in increased evapotranspiration and reduced potential for infiltration.

Finding: The monofill will be unlined.

Finding: A total of ten cells will be constructed over the life of the monofill. The working face receiving the inert materials will comprise, at any one time, an area measuring 120" x 50'. Therefore, the surface of the monofill most vulnerable to infiltration by precipitation at any one time will be kept to a minimum (Maddox & Associates, December 13, 2013; page B-12).

Finding: The monofill is designed to minimize the moisture levels in the material so that the rate of decay and rot will be very slow and will not significantly impact any leachate, if there is any leachate at all that leaves the monofill.

Finding: ADEC regulations state that an unlined landfill may not be located closer than 10 feet above the highest measured level of an aquifer of resource value unless the landfill is constructed two feet or more above the natural ground surface (18 AAC 60.217).

Finding: Under Alaskan administrative regulations, this proposed monofill is exempt from providing groundwater monitoring and corrective action to state agencies, as it is located in an area with 25 inches or less in total precipitation each year, per ADEC regulations (18 AAC 60.820(a)(8)).

Finding: CMS provided a groundwater monitoring plan to verify that the monofill is not impacting the groundwater. EMI found the probability of creating a leachate that will impact the groundwater is so low that in his opinion groundwater monitoring is not necessary and recommends the submitted groundwater monitoring plan be withdrawn and not implemented.

Finding: CMS withdrew their groundwater monitoring plan from the application material. Staff is recommending that a groundwater monitoring plan be required by the Borough Planning Commission and implemented in the conditional use permit.

Conclusion of Law: Based on the above findings the monofill is being designed so that a significant amount of leachate will not be produced; the groundwater level has been determined; no contaminant plume will extend down gradient from the monofill; and there will be minimal infiltration. A condition will be set to implement a groundwater monitoring plan at this site.

Finding: Materials brought to the facility that have not been previously inspected will be deposited onto an impermeable pad for inspection, recyclable materials removed and remaining the non-recyclable material placed in the active monofill cell.

Finding: If prohibited materials are found they will be removed for proper disposal and any contaminants properly cleaned up.

Finding: The applicant states that the following material will not be accepted at this monofill:

- PCBs or other Hazardous Wastes
- Household Waste
- Putrescible Waste
- Liquids

- Compressed Gas Cylinders
- Batteries
- Appliances with CFC/HCFC
- Animal Carcasses
- Petroleum Contaminated Materials

Finding: Alaska Statutes 46.03.900(10)—defines "hazardous waste" as "A waste or combination of waste that because of quantity, concentration, or physical, chemical, or infectious characteristics may: cause or significantly contribute to, an increase in mortality or an increase in serious irreversible or incapacitating reversible illness; or pose a substantial present or potential hazard to human health or the environment when improperly managed, treated, stored, transportcd, or disposed of."

Finding: Material haulers transporting any demolition and/or renovation material to a CRS facility or this monofill must provide the following documentation: (1) A copy of all Hazardous Building Material Surveys for each project that will be bringing their demolition and/or renovation material to the facility. Should the Survey indicate the presence of any hazardous materials, then (2) a letter from the Contractor of each project is also submitted to CRS stating that all hazardous material has been properly removed from the project and there is no hazardous material being brought to the CRS facility. For their operations, CRS defines hazardous material as a material containing any percentage of asbestos.

Finding: Regulated Asbestos Containing Material (RACM) and Non-RACM will be accepted for disposal at the monofill in accordance with all applicable federal and state regulations for packaging, labeling, transport handling and disposal.

Finding: Materials that can be accepted at this monofill are described in the State of Alaska's Solid Waste Regulation, 18 AAC 60.

Finding: The Plan of Operations submitted to ADEC will prevent hazardous waste, as defined by the Federal government (40 CFR 261.3) from being placed in the monofill.

Conclusion of Law: Material brought to the facility is sorted, screened and processed to ensure that the material is free of hazardous waste and putrescible material and/or liquids.

Finding: Testing for potential contaminants from the waste has occurred.

Finding: Leachate modeling identified two potential contaminants of concern: sulfate and manganese. The results predict that the analytes will likely comply with the ADEC's drinking water standards.

Finding: Baseline data for water quality has been provided.

Finding: Seasonal water table elevation fluctuations have been established.

Finding: The site is less than one mile from the Palmer Hay Flats Refuge, which is a major migratory bird refuge in Southcentral Alaska.

Conclusion of Law: With conditions, the proposed monofill should not be harmful to the public health, safety, convenience, and welfare (17.60.100(B)(2)).

(3) That sufficient setback, lot area, buffers, or other safeguards are being provided to meet the conditions listed in subsections (B)(1) through (3) of this section.

APPLICANT'S STATEMENT

Currently on the existing site, there are no permanent or semi-permanent buildings, therefore there are no current setbacks from these buildings. Potential future structures will be placed more than 30 feet from the current Right-Of-Way and therefore setback requirements will not be an issue for these structures.

The ADEC regulations require that waste which is to be placed within the monofill be kept at a minimum of 50' from all property boundaries. Please see the Site Plan for the proposed location of the monofill and for the potential locations of any future structures.

CRS has implemented a minimum 25' setback from the industrial ponds on site. This setback states that no material will be placed or stockpiled within this 25' boundary between the industrial ponds and the rest of the useable property areas. No waste will be placed within 100' of the industrial ponds. This implementation not only reassures the public that the industrial ponds will not be affected by the monofill and its recycle operations, but this also helps CRS protect the industrial ponds. This 25'/100' setback is shown on the attached Site Plan.

The utilization of the natural vegetation and naturally occurring hills of the property will be employed as both visual and noise buffers. The usage of the existing site topography will allow Central Recycling Services to create a natural property/site boundary without the use of extensive fencing. Central Recycling Services will place the inert debris into the 35 acre monofill area without disrupting the current neighboring lands' ecosystems, both agricultural and natural occurring bio-networks.

The cell walls, as show in Sheet 3, the natural topography of the surrounding hills, and litter fences, reduce the possibility of dust and debris from being able to leave the site. The nearest home to the Monofill site is 500 feet with a nearly 300 foot buffer of trees.

The CMS CUP meets the setback requirements of 17.60.

STAFF FINDINGS

Finding: The maximum finished elevation of the monofill will be 162 feet Above Sea Level. The adjacent Glenn Highway has an average finish elevation of 117 feet Above Sea Level, so the maximum height will be a little more than 40 feet above the Glenn Highway. The existing tree covered berm along the Glenn Highway has an average elevation of 130 feet Above Sea Level. The maximum depth of the monofill will be 75 feet with an average depth of 50 feet.

Finding: The site can be screened with the existing berms and by building up the berms and constructing site obscuring fencing. Screening from the western properties will have to be developed as the site is built up.

Finding: Salvageable/recyclable materials that are stored outside for resale must also be screened.

Conclusion of Law: The monofill site can be screened with the existing berms and by building up the berms and constructing site obscuring fencing. Screening will be developed as the site is built up. Salvageable/recyclable material that is stored outside for resale will also be screened.

Finding: ADEC regulations require that monofill waste be set back a minimum of 50 feet from all property lines.

Finding: No material will be placed or stockpiled within 25 feet of the industrial ponds on the site.

Finding: No waste will be placed within 100 feet of the industrial ponds on the site.

Finding: In addition to the monofill, two storage or shop buildings, a scale house, and field office are proposed for the site.

Finding: The site plan depicts the proposed structures in compliance with setback requirements.

Finding: The operation will be required to comply with the maximum permissible sound level limits allowed in MSB Code, per the requirements of MSB 17.61.080 – Noise Standards and MSB 8.52 – Noise, Amplified Sounds, and Vibration.

Finding: The driveway to the site will be secured with a locked gate.

Finding: The site is monitored with camera security systems.

Finding: Only approved contractors will be allowed to bring material to the facility. This is controlled by gates and on-site personnel that will inspect all loads delivered to the facility.

Finding: The public will not be allowed to drop off or dispose of material at the monofill.

Finding: The sale yard will be open to the public with controlled access.

Finding: With conditions, there will be adequate safeguards in place to prevent blowing debris and incidental trash onto adjacent properties and roadways. Additional conditions will be set regarding the handling and storage of materials during wind events.

Conclusion of Law: Based on the above findings, the proposed structures are in compliance with setback requirements, the site will be screened from adjacent right-of-ways and residences, the driveway will be secured with a locked gate, and the site will be monitored with camera security systems (17.60.100(B)(3)).

(4) The conditional use fulfills all other requirements of this chapter pertaining to the conditional use in this section.

APPLICANT'S STATEMENT

Yes, this conditional use does fulfill all other requirements of MSB Chapter 17.60 regarding the conditional use.

STAFF FINDINGS

Finding: The application material adequately addresses the impacts of the climate, geology, hydrology and geography of the site and the impacts to surrounding land uses.

Finding: According to documentation and studies the proposed monofill site is located where the topography, geology, hydrology and soil are adequate for protection of ground and surface water quality.

Conclusion of Law: Based on the above finding, the conditional use does fulfill all other requirements of this chapter (17.60.100(B)(4)).

Section 17.60.110 Junkyards and Refuse Area Standards.

(A) No junkyard or auto wrecking yard shall be established or operated unless the wrecking yard is completely obscured from the view of any traveled or public right-of-way. The permit may require the junkyard or auto wrecking yard not within a building to be contained within a continuous solid fence no less than eight feet in height, if such requirement is necessary to prevent the unsightly display of the yard or for public safety purposes. Fencing may be of one or a combination of the following:

(1) Conventional solid wood or metal fencing;

(2) Evergreen or other natural planting sufficient to provide year round screening;

(3) Earthen berm or topography.

(B) In all cases, fencing provided shall be continuous and of sufficient density to provide visual screening required by this chapter on a year-round basis.

APPLICANT'S STATEMENT

See the above section on Visual Screening and Sheet 6 Cross Section of the drawings and Sheet 1 Individual Typical Section.

STAFF FINDINGS

Finding: The site is required to be visually screened on a year round basis from the view of any traveled or public right-of-way. The site must be screened from the Glenn Highway, the section line easement on the west side of the property, and the section line easement running east/west through the property.

Finding: The maximum finished elevation of the monofill will be 162 feet Above Sea Level. The adjacent Glenn Highway has an average finish elevation of 117 feet Above Sea Level, so the maximum height will be a little more than 40 feet above the Glenn Highway. The existing tree covered berm along the highway has an average elevation of 130 feet Above Sea Level. The finished revegetated height of the monofill will be above the berm on the south side, adjacent to the Glenn Highway.

Finding: The monofill can be screened with the existing berms and by building up the berms and constructing site obscuring fencing. Screening from the section line easements and properties on the west side will have to be developed as the site is built up.

Finding: The proposed monofill is an industrial use. The monofill can be screened with the existing berms and by building up the berms and constructing some site obscuring fencing.

Screening from the section line easement and western properties will have to be developed as the site is built up.

Finding: Salvaged/recyclable materials that are stored outdoors at the resale lot must also be screened.

Conclusion of Law: Based on the above findings screening of the site will be accomplished by using the existing topography and berms, building up berms and installing site obscuring fencing (17.60.110(A) & (B)).

STAFF RECOMMENDATION

Staff recommends approval of the conditional use permit for the operation of a monofill for the disposal of inert construction and demolition debris, including Regulated Asbestos-Containing Material (RACM) and Non-Regulated Asbestos-Containing material (Non-RACM) and an outdoor storage yard for salvageable/recyclable materials on 17N01E18C010 (2840 S. Glenn Highway) and 17N02E19B006 (2560 S. Glenn Highway). The application meets all the standards in MSB 17.60.100 and 17.60.110. Staff is recommending approval of this permit with the following conditions:

1. It is the responsibility of the property owner and operator to identify and comply with all applicable local, state, and federal regulations applicable to this development and obtain all necessary authorizations and permits and update as appropriate.

2. Upon issuance of a permit under MSB Chapter 17.60, the permittee shall provide and maintain all necessary documentation to demonstrate continued compliance with permit conditions.

3. The property owner and the permittee shall be responsible for maintaining all aspects of the operation, improvements, and development, and the site in compliance with the terms and conditions of the permit and all applicable local, state, and federal requirements.

4. Authorized representative of the borough shall be allowed to inspect the site at reasonable times for the purpose of monitoring compliance with all permit conditions. Upon reasonable notice from the Borough, the permittee shall provide necessary assistance to facilitate authorized inspections.

5. Except as otherwise specified by code, the privileges and requirements of a conditional use permit shall run with the land, subject to the following requirements: Within 90 days of recording the transfer of ownership of the subject land, the new owner shall provide written notification and a signed acknowledgement that the new owner assumes responsibility for compliance with the requirements of the permit.

6. If the operation expands or alters, an amendment to the conditional use permit shall be required.

7. The operation shall be limited to what is described in the development plan submitted to the Matanuska-Susitna Borough and the Plan of Operations submitted to the Alaska Department of Environmental Conservation.

8. An area no larger than 120' x 50' shall remain uncompacted at any one time.

9. The maximum square footage that shall be exposed and not covered at any one time during the monofill operation shall be 25,000 square feet.

10. At a minimum, the monofill material shall be covered with soil weekly.

11. Immediately after the tire bales used for the side walls are installed they shall be covered with topsoil and seeded for revegetation.

12. A remote weather station shall be installed at the site to monitor wind speed. The weather station shall be set up where the wind flows freely and is not influenced by nearby objects or topography.

13. When sustained wind conditions on the site exceed 10 mph, waste material shall not be deposited at the site.

14. When sustained wind speeds exceed 15 mph, all open areas shall be covered with soil, secured with tarps, or other appropriate measures until sustained winds decrease to less than 10 mph.

15. The applicant shall install catch fences downwind of active monofill cells at all times. The fencing mesh shall be a maximum of one inch (1") in size.

16. At the end of each day the stockpiled daily cover shall either be contained within a covered trailer or completely covered with tarps that are secured to ensure that material does not become airborne.

17. The site shall be monitored daily for windblown material. If materials are found to have blown off-site a corrective measures plan shall be submitted to the Borough for approval.

18. If material is windblown onto adjacent properties, reasonable attempts shall be made to obtain permission to gain access to these properties for debris removal

19. The site shall be visually screened on a year round basis from all traveled or public rights-of-way and from the residential properties on the west side of the property.

20. The maximum finished elevation of the monofill shall not exceed 162 feet Above Sea Level.

21. Upon completion, the monofill shall be covered with two feet of topsoil, seeded, and sloped as described in the development plan.

22. Should the operation be modified as a result of the Glenn Highway Reconstruction Project, an updated site plan and plan of operations shall be submitted to the Borough.

23. The bottom of the monofill shall not be located closer than 10 feet above the seasonal high water table.

24. If it is found that groundwater has been contaminated, a corrective measures plan shall be submitted to the Borough for approval.

25. The Groundwater Monitoring Plan prepared for this site by TERRASAT, Inc., dated May 17, 2013, shall be implemented and maintained, except that a final laboratory report resulting from a release investigation shall be submitted to the Borough within 48 hours of receiving the report.

26. Materials that can be accepted at this monofill are described in the State of Alaska Solid Waste Regulations, 18 AAC 60.

27. The following materials shall not be accepted at this monofill: PCBs or other hazardous wastes, household waste, putrescible waste, liquids, compressed gas cylinders, batteries, appliances with CFC/HCFC, animal carcasses, and petroleum contaminated materials.

28. Materials brought to the facility that have not been previously inspected by qualified personnel shall be deposited onto an impermeable pad for inspection prior to being deposited in the active monofill cell.

29. If prohibited materials are found, they shall be properly handled and disposed of in accordance with all state and federal laws.

30. Regulated Asbestos Containing Material (RACM) and Non-RACM shall be handled and disposed of at the site in accordance with state and federal regulations for packaging, labeling, transport handling and disposal.

31. Monofill waste shall be set back a minimum of 50 feet from all property lines.

32. No waste shall be placed or stockpiled within 100 feet of the industrial ponds on the site.

33. Only previously approved haulers shall be allowed to bring material to the facility.

34. The operation shall comply with the maximum permissible sound level limits allowed in MSB Code, per the requirements of MSB 17.61.080 – Noise Standards and MSB 8.52 – Noise, Amplified Sounds, and Vibration.

35. The site shall be gated and locked when not in operation. All visitors to the site must check in with personnel.

36. Hours of operation shall be limited to 7 a.m. to 7 p.m., Monday through Saturday, May through September and 8 a.m. to 5 p.m., Monday through Saturday, October through April.

37. Environmental and Pollution Insurance shall be maintained in the amount of $1 million single with a minimum $5 million aggregate.

38. This conditional use permit shall expire December 31, 2045.

39. The owner shall provide copies of all permits issued by state and federal agencies to the Matanuska-Susitna Borough prior to commencement of the permitted use. The owner

shall also provide to the borough a copy of every application for an amendment to any such permit at the time the application is filed with the permitting agency, and a copy of any amendment approved by the permitting agency shall be provided to the borough within five days of issuance.

40. This permit has been approved by the Matanuska-Susitna Borough Planning Commission. The decision may be appealed within 21 days of the date of approval by the Planning Commission in accordance with MSB 15.39 – Board of Adjustment and Appeals.

Should the Planning Commission choose to deny this conditional use permit, findings for denial must be made.

CENTRAL MONOFILL SERVICES

CONDITIONAL USE PERMIT APPLICATION

JANUARY 15, 2014

CENTRAL MONOFILL SERVICES

Anchorage
311 N. Sitka Street
Anchorage, AK 99501

Fairbanks
1301 Wells Street
Fairbanks, AK 99701

Since 2009 the Central Companies have been expanding waste management and recycling services across Alaska. We currently have facilities in Anchorage, Fairbanks and Salcha. We recycle waste that had been historically landfilled in Alaska. Our services lower waste disposal costs and provide locally manufactured recycled content materials.

We are proposing to bring these services to the Mat-Su Borough with a recycling and C&D waste disposal facility located at the 118 acre site located at 2480 and 2560 S. Glenn Hwy. Municipal waste landfills, such as the Matanuska Susitna Borough Central Landfill, are expensive public facilities that often have to be funded by the public for expansion and closure outside of normal rates charged to the users. Due in part to the rising costs to build and manage municipal waste landfills and governmental requirements to divert waste from municipal landfills, public and private C&D Recycle facilities have opened around the country. The first C&D Recycle facility in Alaska was opened in 2009 by Central Recycling Services (CRS). These facilities accept inert waste, C&D, and commercial waste materials that have traditionally just been disposed of in a municipal landfill. Inert C&D debris can be generally characterized as the parts and pieces that make up your house; carpet, wood, metal, glass, concrete, etc., materials which can be reused or recovered from the waste stream and remanufactured into new products. These materials become waste during renovation, new construction and demolition of houses, commercial buildings, industrial facilities, etc. Some manufacturing facilities generate similar waste during production of new goods. The recyclable portion of the waste stream handled by the Central Companies does not contain any putrescent or regulated municipal wastes which are required to be disposed in a municipal landfill. Putrescent wastes are those that rot and rapidly decompose, and are typically household garbage. In accordance with the Alaska Department of Environmental Conservation (ADEC), regulations the inert portion of the waste stream can also be disposed of at a Monofill which is a type of Landfill that has different design requirements and regulations than a municipal waste landfill. The Monofill design requirements are particular to ADEC approved inert debris. Lawsuits against the EPA in the 1990's, resulted in settlement and the promulgation of today's landfill regulations. Subsequent studies done by the National Demolition Association and others support the existing regulations and have found that properly designed, maintained and operated demolition landfills, such as the monofill CMS is proposing, pose no significant threat to the environment and are the most economical and environmentally sound method to manage that portion of the inert waste that cannot be recycled.

CENTRAL MONOFILL SERVICES

Anchorage
311 N. Sitka Street
Anchorage, AK 99501

Fairbanks
1301 Wells Street
Fairbanks, AK 99701

The significant cost to build a full scale commercial C&D Recycle Facility limits the viability of developing such a facility in the MSB. However, construction and other growth in the Valley have created a demand for our recycled and surplus goods and for commercial recycling services in the Valley. We have identified the need for our services in the Valley to collect and recycle inert C&D wastes, but also found it would not be cost effective without the ability to dispose of the non-recyclable residual wastes at the same facility. CRS recycles over 75% of the waste material received. Some of these recycled materials are sold into the local markets as new building materials and some are exported as commodities like metals and plastics. The 25% that is left over after recycling is considered the residual waste. This residual waste can be disposed of in an ADEC permitted monofill. In 2011 the Central Companies started looking for properties in the MSB that could be used for the storage, sales and distribution of recycled goods, collection of recycled materials and development of a monofill for the non-recyclable waste. Multiple properties were evaluated and in late 2012 the subject site selection was finalized and the property purchased by Central Monofill Services (CMS).

During the site selection process we consulted with the MSB staff to verify the MSB Code requirements for the proposed recycle facility and monofill. MSB Staff determined that the Recycle Facility component of our operation fell under the definition of a Junkyard and thus would require a Conditional Use Permit per MSB 17.60. Staff also determined the monofill component would also require the Junkyard Permit because the monofill would constitute the "outdoor storage... of used building materials..." per 17.60. Within 2 miles of the CMS site there are two other monofills and a recycling facility none of which have an MSB CUP. One of those monofills is within the City of Palmer and the other is operated by the MSB under Code Section 8.05 Solid Waste. The facility within the City of Palmer was recently granted a renewal of their City of Palmer CUP. The MSB operated VCRS recycle facility adjacent to the Central Landfill does not have a CUP for a Junkyard.

CMS has listened carefully to concerns expressed by the public and some commissioners during a prior submission and respectfully submits this revised package to address those concerns. In addition to having this design and proposal reviewed by a nationally recognized hydrogeologist to address water concerns, CMS has met with Alex Strawn to address staff concerns. CMS submits this CUP application and attachments to address the requirements described in MSB 17.60 and other requests made by staff. The MSB does not have design standards or specific CUP standards for a recycle facility or monofill. The facility has been designed to meet the State of Alaska DEC standards for an inert waste monofill. ADEC has approved the proposed Monofill design. Should you have further questions or clarifications please ask the applicant during the hearing.

Application for a Junkyard Conditional Use Permit – MSB 17.60

MATANUSKA-SUSITNA BOROUGH
Planning and Land Use Department
Permit Center
350 East Dahlia Avenue • Palmer, AK 99645
Phone (907) 745-9822 • Fax (907) 745-9876
Email: PermitCenter@matsugov.us

APPLICATION FOR A JUNKYARD CONDITIONAL USE PERMIT – MSB 17.60

Carefully read instructions and applicable borough code. Fill out forms completely. Attach information as needed. Incomplete applications will not be processed.

Application fee must be attached:
_____**$500** for **Junkyard Conditional Use Permit**
Prior to the public hearing, the applicant must also pay the mailing and advertising fees associated with the application. Applicants will be provided with a statement of advertising and mailing charges. Payment must be made prior to the application presentation before the Borough Planning Commission.

Subject Property Township: 17N, Range: 02E, Section: 18 + 19, Meridian S
MSB Tax Parcel ID#: 19142 and 20725
SUBDIVISION: _____ BLOCK(S): _____, LOT(S): C10 + B10
STREET ADDRESS: 2480 S. Glenn Hwy and 2560 S. Glenn Hwy, Palmer, AK
(US Survey, Aliquot Part, Lat. /Long. etc) _____

Ownership A *written authorization by the owner must be attached for an agent or contact person, if the owner is using one for the application.* Is authorization attached? o Yes o No X N/A

In order to grant a conditional use permit under MSB 17.60, the Planning Commission must find that each of the following requirements have been met. Explain the following:	**Attached**
1. Is the conditional use compatible with and will it preserve or not materially detract from the value, character and integrity of the surrounding area?	Yes
2. Will the granting of the conditional use permit be harmful to the public health, safety, convenience and welfare?	Yes
3. Are sufficient setbacks, lot area, buffers and other safeguards being provided?	Yes
4. Does the conditional use fulfill all other requirements of MSB Chapter 17.60 pertaining to the conditional use in this section?	Yes

Permit: *Application for a Conditional Use Permit- MSB 17.60*
Applicant: *Central Monofill Services*
Date Submitted: *January 15, 2014*

Supplemental Information	**Attached**
1. Number of employees proposed to work on largest work shift	Yes
2. Hours of operation	Yes
3. Noise mitigation measures	Yes
4. How will contaminated materials be handled and disposed of at this site?	Yes
5. Total square footage or acreage of this property	Yes
6. Total square footage or acreage for this use on this site	Yes
7. Are there other existing or proposed uses on this site or will this operation be the sole use of the property? *If there are other uses on this property, provide a description.*	Yes
8. Use(s) of any proposed building(s) associated with this operation	Yes
9. Copy of Hazardous Material Plan for the operation, if applicable	Yes
10. Type of equipment to be used at this site	Yes
11. What type of containment systems will be in place at this site?	Yes
12. What type of non-permeable surface will be in place at this site?	Yes
13. What will be the daily traffic generation for this use?	Yes
14. Attach a written description of the buffering that will be provided at this site to meet the standards in 17.60.110. *This may include conventional solid wood or metal fencing; evergreen or other natural planting sufficient to provide year-round screening; and* earthen *berm or topography.*	Yes

SITE PLAN – Attach a detailed, to scale, site plan clearly showing the following information:	**Attached**
1. Proposed and existing structure(s) on the site. Indicate which structure(s) will be used for this use. Draw lot dimensions and indicate setback distance of structure(s) from the lot lines, rights-of-way, and waterbodies.	Yes
2. Dimensions of all structures	Yes
3. Location of the use or uses to be made of the development	Yes
4. Location of other uses on the site	Yes
5. Signage – Existing and Proposed	Yes
6. Location and dimensions for all access points to and from the site to public rights-of-way or public access easements	Yes
7. Buffering – Fences, trees, topography or berms	Yes
8. Drainage	Yes
9. Vehicular and pedestrian circulation patterns	Yes
10. Exterior site lighting	N/A
11. Location and dimensions of parking areas to be provided	Yes
12. Location of other uses on the site	Yes
13. Scale and north arrow	Yes

Permit: *Application for a Conditional Use Permit- MSB 17.60*
Applicant: *Central Monofill Services*
Date Submitted: *January 15, 2014*

OWNER'S STATEMENT: I am owner of the following property:

MSB Tax parcel ID #(s) 19142 and 20725 and, I hereby apply for approval a junkyard conditional use permit on that property as described in this application.

I understand all activity must be conducted in compliance with all applicable standards of MSB 17.60 and with all other applicable borough, state or federal laws.

I understand that other rules such as local, state and federal regulations, covenants, plat notes, and deed restrictions may be applicable and other permits or authorization may be required. I understand that the borough may also impose conditions and safeguards designed to protect the public's health, safety and welfare and ensure the compatibility of the use with other adjacent uses.

I understand that it is my responsibility to identify and comply with all applicable rules and conditions, covenants, plat notes, and deed restrictions, including changes that may occur in such requirements.

I understand that this permit and zoning status may transfer to subsequent owners of this land and that it is my responsibility to disclose the requirements of this status to the buyer when I sell the land.

I understand that changes from the approved conditional use permit may require further authorization by the Borough Planning Commission. I understand that failure to provide applicable documentation of compliance with approved requirements, or violation of such requirements will nullify legal status, and may result in penalties.

I grant permission for borough staff members to enter onto the property as needed to process this application and monitor compliance. Such access will at a minimum, be allowed when the activity is occurring and, with prior notice, at other times necessary to monitor compliance.

The information submitted in this application is accurate and complete to the best of my knowledge.

Project Description

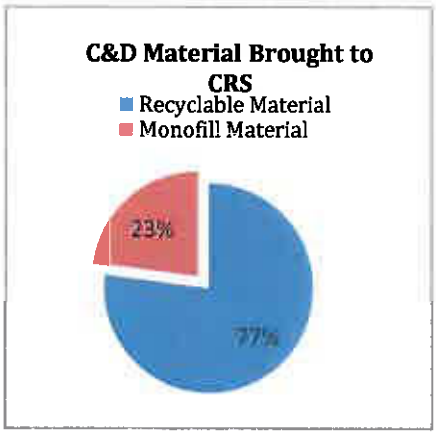
Project Need

Construction activities in the United States consume 40% of the raw materials used.[1]/[2] Construction waste accounts for roughly 30% of the solid waste disposed of in the United States. These large percentages place a burden on the environment to create new raw materials and dispose of discarded material. Today through reuse and recycling these percentages can be greatly reduced. Increases in reuse and recycling can lower construction costs by creating cheaper recycled content construction materials. Decreasing the amount of material landfilled by reuse and recycling typically lowers public costs by reducing pressure on traditionally expensive municipal landfills.

The need for greater waste diversion via reuse and recycling in Alaska is well documented. The Matanuska-Susitna Borough Solid Waste Management Plan recommends the borough to encourage the public to divert more materials from the landfill. This same plan indicates the diversion of 12% Construction and Demolition (C&D) waste from the Municipal Solid Waste Cell will result in a 11.3% cost savings to the Central Landfill.[3]

Over the last five years through public/private cooperation the state of Alaska and many local governments have begun accepting recycled content materials in new construction. This has led to the development of the Construction and Demolition (C&D), recycling industry in Alaska.

The C&D Recycling industry takes the construction waste once destined for the landfill and processes/recycles the waste into new recycled content manufactured products. The new recycled content products take the place of the virgin raw materials that once had to be used. Good examples of this is taking excess or demolished brick and concrete from a construction site and recycling into new aggregate instead of mining aggregate from a gravel pit, or taking waste wood from a construction site and selling it for reuse.



[1] LeBlanc, Rick, The Importance of Construction & Demolition Recycling, 11/11/2013; http://recycling.about.com/od/Construction/a/The-Imporance-Of-Construction-and-demolition-recycling.
[2] United States Environmental Protection Agency, Municipal Solid Waste in The United States, 2009 Facts and Figures
[3] CH2M Hill, Final Report: Solid Waste Management Plan, Year 2002, Prepared for Matanuska-Susitna Borough, May 2002.

Today's C&D recycle facilities often reclaim over 75% of the waste materials they receive. That means 75% of the construction material that once went to the landfill is now remanufactured, recycled or otherwise repurposed keeping it out of the landfill.

The 25% of construction debris residual waste left after recycling has no value and still needs to be landfilled. This residual waste material has been through multiple processes that help insure this waste is free of hazardous wastes, putrescent waste or other regulated types of waste. This recycle facility residual waste can be disposed of in an inert waste monofill. A monofill is a type of landfill that accepts only ADEC approved inert waste. In this case, the left over recycle residue is one of the types of inert waste. A monofill has different regulatory requirements than a traditional municipal landfill. Municipal landfills have to be designed to accept practically any type of waste. The waste from municipal waste garbage trucks and the public dumping in a municipal landfill are not inspected and can contain anything a person puts in the trash. Recycle facility residue or even C&D debris going to a monofill is from a known source and in accordance with EPA regulations has been inspected for hazardous materials. The monofill has less stringent design requirements than a municipal landfill because the waste material is from a known source and free of hazardous wastes, liquids and putrescent materials that would create problematic leachate. A monofill is less expensive to construct and operate than a municipal landfill. Municipal landfills such as the MatSu Central Landfill are constructed and operated with public monies. Placing recyclable construction material or recycle facility residue in a Municipal Landfill it adds to the public burden of paying for disposal. The Mat-Su Borough Solid Waste Management Plan, Year 2002 Update indicates the public costs associated with waste disposal can be reduced at an almost 1 to 1 ratio by recycling and disposal of inert waste at a private monofill instead of in a lined Municipal landfill.

To be cost effective, recycle facilities, disposal options, reusable materials and recycled content materials have to be close to market. Stigmas associated with recycling and landfilling challenge operators to find acceptable sites to locate these facilities. In order to make recycling viable the facilities have to be centrally located to where the waste is produced, recycle materials are used and byproducts disposed of. By moving any of those three criteria too far away from market the demand decreases and cost increases eliminate the viability of recycling. If recycling costs more than new raw materials or traditional methods of disposal it has been well documented that the public will utilize the least cost method even if it results in increased waste of raw materials.

The large scale recycle services provided by CRS are currently viable within the Municipality of Anchorage but not in the Matanuska Susitna Borough, (MSB). There is demand for these services in the MSB, but it is currently not viable to haul the recyclable waste materials to Anchorage for recycling and run an empty truck back to the MSB. If trucks can haul recyclable material from the MSB to the Anchorage facility and haul recyclable materials and the residual waste back to the CMS monofill disposal site, the recycling becomes viable. The CUP is needed to allow CRS to collect and transfer the

materials on site to larger trucks for hauling to Anchorage, to store or resell recycled or reusable materials from Anchorage and to place the residual waste in the CMS Monofill.

The benefits of this CUP are:

- Reduced Disposal Cost
- Reduced Construction Costs
- Increase in Reuse of Materials
- More options for building products
- Decrease in dependence on virgin raw materials
- Decrease in volume of material landfilled
- Reclamation of gravel pit industrial property into farm land or park space
- Creation of Jobs in the MSB
- New taxable business in the MSB

CRS Anchorage Recycling Facility

Project Summary

Central Monofill Services (CMS), intends to establish a recycle facility on the subject property where construction and demolition (C&D) materials can be collected and recycled and the residual waste disposed. Salvageable and reusable materials will be staged on site for resale. Some recyclable waste will be hauled to Anchorage to utilize the large CRS recycle processing facility. CRS will process the recyclable waste at the Anchorage recycle facility.. The recovered waste is manufactured into new recycled content products. Some of these recycled content products will be backhauled to the CMS Palmer site for resale. The CMS site will also operate an ADEC approved monofill to properly dispose of non-recyclable (Residual) C&D material.

Permit: *Application for a Conditional Use Permit- MSB 17.60*
Applicant: *Central Monofill Services*
Date Submitted: *January 15, 2014*

Construction and Demolition (C&D) Debris Description

The simplest way to describe C&D materials is to look at your house or office. C&D waste is generated from the materials used to build your house, office etc. These are materials you are exposed to every day, wood, carpet, cabinets, etc.

Construction and Demolition Debris for Recycling

The "Construction" portion typically refers to the leftover or waste material from new construction of homes and buildings. The lumber cutoffs, pipe ends, empty containers, packaging, scraps of flooring, concrete waste, etc.

"Demolition" debris is usually material generated during the removal or renovation of a building. Often times this is the entire structure including roofing and the foundation.

The handling, removal and disposal of these materials are regulated by OSHA and the EPA to insure worker safety and environmental protection. These are the same materials that each person lives with and is in contact with on a daily basis in their homes. These building materials are in a constant state of aging and degradation in a home similar to the degradation process of the same type of waste in a monofill.

Reuse, Repurpose, Recycle

After the identification and removal of hazardous materials from the waste stream, the first step to C&D Recycling is to salvage for reuse as much as possible from the potential waste stream. C&D often contains useable items, including everything from doors and windows to structural materials and furniture. These reusable items are removed and set aside for resale. These items are sold for less than new materials. Repurposed materials are those removed from the waste stream and with little modification are used for a new purpose other than originally manufactured. Examples are steel culvert pipe repurposed into fence posts or fire pits, broken concrete used as patio pavers. Material going through a recycle facility are

CRS Debris Sort Line

separated into different recyclable materials of value such as but not limited to: wood, certain grades of plastic, metals, concrete and brick, glass, cardboard etc. Some of these materials are resold as a commodity to be reprocessed by others such as, scrap metal that is sold back to a steel mill to be melted into new steel. Other recyclable material is reprocessed locally into new recycled content materials. Items reprocessed locally include; glass crushed into new aggregate, tires made into structural tire bales, concrete and brick crushed into new road aggregate and wood ground into mulch or made into wood pellet fuels.

Salvaged Wood

Reused, Repurposed and Recycled materials are kept out of the landfill and replace the use of new materials thus reducing the waste of our natural resources.

Site Selection

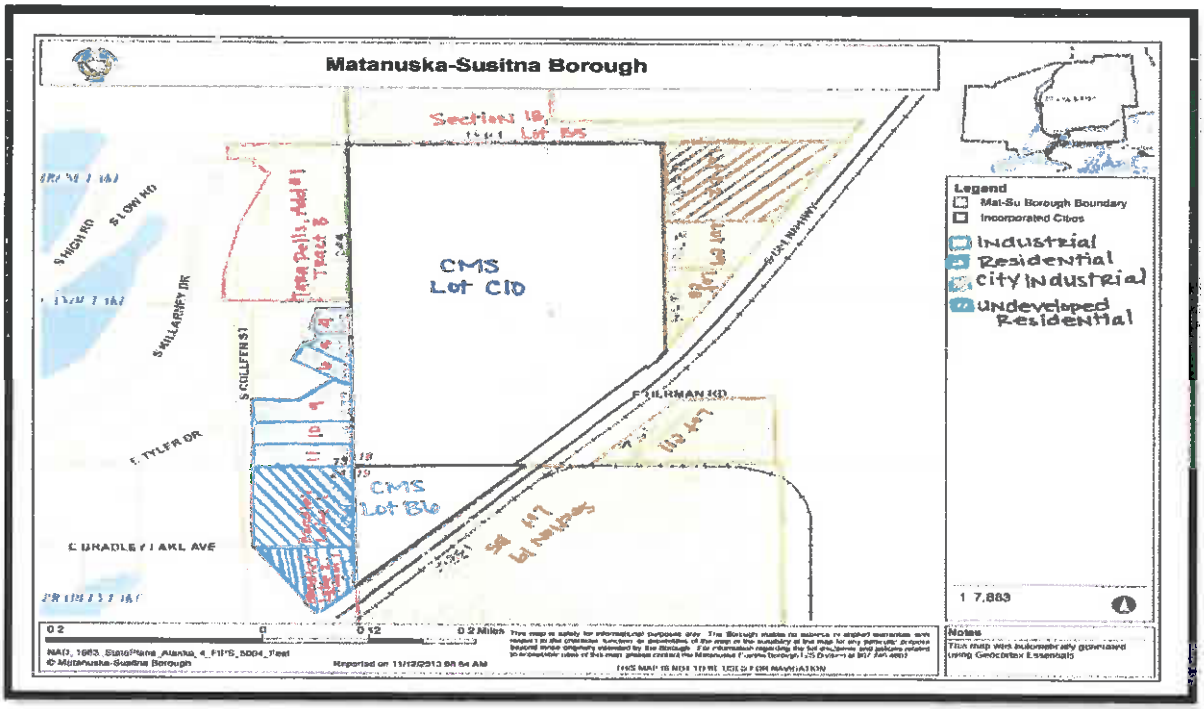
Aerial Photograph of 17N02E18C010 and 17N02E19B006
Proposed Monofill location highlighted

With an identified need for C&D Recycling in the MatSu Valley, CMS set out to find a location to provide this service. Several years have been spent trying to find a property that was for sale and in a suitable location.

To make the recycling economically viable it must be in a location close to the markets to reduce hauling costs on both the inbound and outbound materials. This economically viable distance was identified to be no further than Seward Meridian up the Parks Highway or beyond Fishhook on the Glenn Highway.

Other criteria included a site at least 20 acres in size, no wetlands or streams, access onto a main road, not in a residential neighborhood and with topography suitable for a fill site. The criteria reduced suitable sites down to only a couple available. Other available sites were priced to be major commercial developments or for their considerable gravel reserves.

The Selected site, lots 17N02E18C010 and 17N02E19B006, located along MP 38 of the South Glenn Highway belonged to Granite Construction Company. This site met the above criteria and was for sale. This site is a gravel pit that has been mined since the early 1990's. The 118 acre property had been substantially mined leaving roughly half the property a large depression and half the property mined into industrial ponds. This site had infrastructure and good access in place to support the recycle facility and monofill and due to the mining activities the site was in a developed state.



Proposed CMS Site Showing Adjacent Property Types

Further investigation into the selected site located at MP 38 South Glen Highway found other significant advantages to locating a recycle facility and monofill on this site.

- 76% of surrounding property is industrial
- Main access directly onto the Glenn Hwy
- Central location close to both Palmer, Wasilla and the Parks/Glenn Interchange
- Existing industrial use
- Permitted gravel extraction created required buffers and screening

No other sites were available meeting the selection criteria. Besides being the only site available the selected property is an ideal candidate due to the existing industrial use of the site and the majority of bordering properties being compatible industrial properties.

Date Submitted: *January 15, 2014*

Comprehensive Plan Review

CMS reviewed the Matanuska-Susitna Borough Comprehensive Development Plan (2005 Update) and Matanuska-Susitna Borough Core Area Comprehensive Plan (2007 Update). These plans manage land use to limit residential and commercial sprawl, limit proximity of incompatible uses, and to encourage uses that support one another. The selected site has been an industrial material extraction site and our proposed new operation is industrial in nature. This CUP application and CMS's proposed operation does not change the land use of this property. If the type of land use has not changed, the CUP would not create any compatibility issues. Residential, recreational or agricultural property is not being changed to industrial. Industrial property is staying industrial. Low Density residential property makes up less than 25% of the surrounding properties.

In review of the Comprehensive Plan's the following applicable policies were found to support the CMS CUP application.

(2007 Update), page 44
Policy 1-J: Encourage light industrial parks

Discussion: *The Core Area does not have and is not expected to attract much heavy industry, not including earth materials extraction sites. However, the Core Area already has pockets of light industrial uses such as outdoor storage, construction yards and shops, building materials supply, garage and outdoor vehicle storage yards, warehousing, utility buildings, miscellaneous outdoor storage, etc. These industrial uses are necessary and a good fit for the local economy, with good growth potential. Demand for sites for industrial uses will increase as the Core Area's economy matures. Even so, industry will remain a modest land use in the overall picture.*

These light industrial uses are generally mutually compatible. They tend to have similar locational requirements, such a good highway access and public utilities, and separation from residential neighborhoods, schools and recreation facilities, and public institutions. Designating sufficient well-situated tracts for light industry will help create a more attractive climate for these activities by enabling them to operate efficiently and with minimal conflict with other ***uses. Restored earth materials extraction site with good highway access can be prime candidates for light industrial uses.***

(2007 Update), page 46
Policy 1-M: Collaborate with operators of large earth materials extraction sites to plan for site reclamation and re-use after earth materials extraction activities are finished.

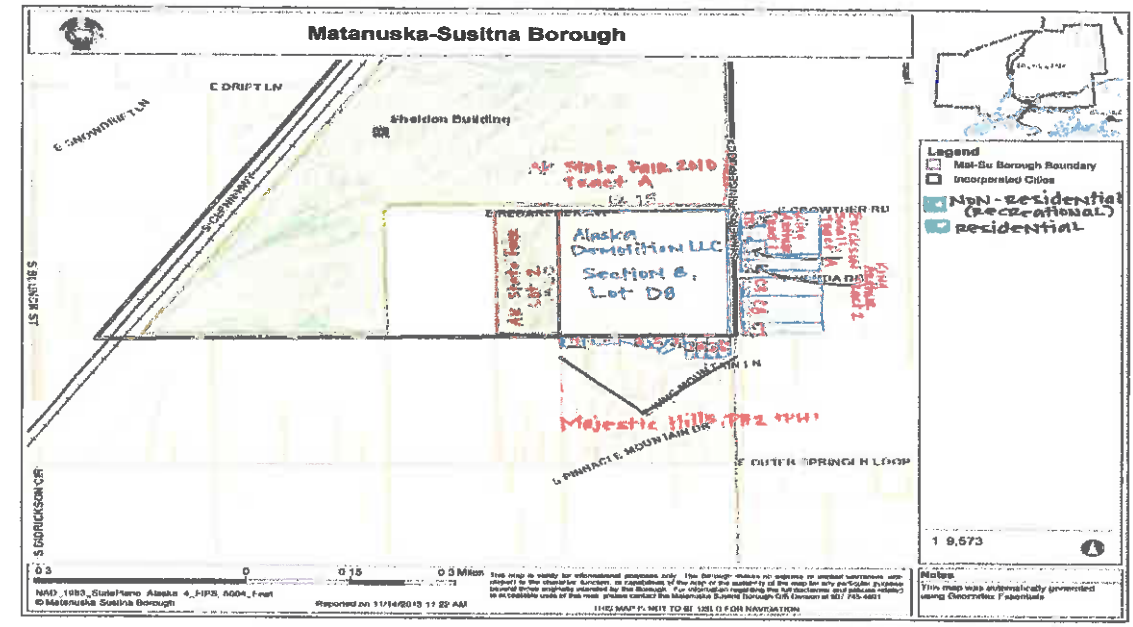
Discussion: *Earth materials extraction sites – gravel and sand pits – are an extensive active interim land use in the Core Area. Several former sites have been redeveloped or await redevelopment. Earth materials extraction is expected to continue as a local industry, with additional sites being put to that interim use in the future.*

Permit: *Application for a Conditional Use Permit- MSB 17.60*
Applicant: *Central Monofill Services*
Date Submitted: *January 15, 2014*

> *Rising land values will enhance the development potential of former sites which often become prime real estate for new uses. Redevelopment of these sites makes good use of the borough's land base and enhances the value and economic potential of nearby properties.*
>
> *This policy proposes that the borough work jointly with property owners, consistent with borough ordinances, to plan for redevelopment of these sites for productive and profitable reuse. The borough can facilitate redevelopment by ensuring that earth materials extraction is managed in a manner that conserves future redevelopment options and by providing essential public infrastructure for redevelopment.*

Many Goals of the comprehensive plans are to protect natural resources, develop green space and preserve agricultural land. These goals can be met with approval of this CUP. This CUP will not change the type of land use in the interim and as the monofill is completed, green space or agricultural land will be created on the top of the fill. Creation of this green space or agriculture land meets goals of the comprehensive plans. Many other developments could be proposed for this property that would require no MSB permitting, and not protect natural resources. The Recycle Facility and Monofill can be developed with proper engineering and operational controls to protect natural resources and public health. Two other C&D Monofill's have operated within 2 miles of the subject site for over 10 years with no known adverse impact to public safety, health or natural resources. These other monofill accept C&D waste but do not perform the recycling, sorting or processing of the waste that leads to the waste diversion. This additional processing also insures any hazardous or prohibited items are removed prior to disposal.

Permit: *Application for a Conditional Use Permit- MSB 17.60*
Applicant: *Central Monofill Services*
Date Submitted: *January 15, 2014*



Alaska Demolition LLC Site Adjacent Property Types

The (2007 Update) indicates that only 2.6% of MSB land is Industrial compared to the Municipality of Anchorage (MOA), with 6.8%. Reductions to existing industrial land will only further reduce the economic potential of the MSB. The subject site and CUP should be compared to similar operations that exist in the MSB for compatibility with surrounding uses.

Table of Surrounding Land Use at Similar Monofill Sites in Alaska

	Total Acres	Residential	Recreational/ State Fair	Undeveloped	Industrial	Agriculture
MSB Central Landfill	620	310	310	0	0	0
Alaska Demo C & D Monofill	38.8	19.4	19.4	0	0	0
Central Monofill Salcha Site	40	20	0	10	0	10
Central Monofill Proposed Site	118.9	16	0	12.5	90.4	0

If existing comparable operations in the MSB which have greater interface with neighboring residential neighborhoods or recreational users have not created conflicts, environmental issues or land use incompatibilities it would be reasonable to say this proposed CUP can be compatible with the goals of the comprehensive plans.

On two separate occasions, once in 2003 and again in 2013, the City of Palmer granted a CUP to Alaska Demolition for the Rebarchek C&D Monofill. [4] On both occasions the City of Palmer, Planning and Zoning Commission determined the C&D Monofill to be in accord with both the borough and city comprehensive plans. This property is bordered 50% by Mat Su Borough developed residential property. To our knowledge, the MSB did not oppose this City of Palmer CUP or request environmental protections be considered even though this Rebarchek C&D Monofill clearly impacts the MSB and its residents.

The (2005 Update) has many goals to protect natural resources, public safety and health. To insure these goals can be met a thorough environmental review of the project was performed. The review, contained in the CUP application, has found this CUP can be issued and meet the applicable goals set forth in the Land Use Plans. There will be no environmental, health, safety or quality of life impacts to residents.

Complaints and arguments from residents that this property is a park and they are losing recreational space are invalid. Residents that have been recreating on this site have been trespassing on private property. However, the fact they have been able to enjoy neighboring Industrial property indicates a compatible land use.

Environmental Review

CMS reviewed the subject site for various natural resource and environmental concerns. Concerns discovered were all found to be manageable with proper engineering controls and work practices.

The status of the onsite industrial ponds was reviewed and determined to not be Waters of the US, Wetlands or navigable waters only manufactured industrial ponds. Hemlock Scientific performed a wetlands review and the Regulatory Division of the United Stated Army Corps of Engineers (USACE) was asked for a Jurisdictional Determination on the subject property. The USACE Jurisdictional Determination (JD) was received July 25th, 2013 and is attached. The JD determined that the property did not contain wetlands or waters of the United States under Corps jurisdiction.

The property was determined to be a true pit with all surface water flows into the property. The only surface flow on or off the property is the industrial ponds that adjoin adjacent parcels. No surface flow was found in or out of the industrial ponds.

Concerns had been raised with Granite's prior mining into the water table that created the ponds. MSB changes to the earth material extraction regulations shuttered mining in the water table in 2011 on this property. Complaints had been made about possible changes to the elevation of the aquifer and nearby lake due to Granite's mining operations. The basis

[4] Supplement to Conditional Use Application, Submitted by Alaska Demolition LLC, Concerning the Palmer Reclamation Site (aka Rebarcheck Pit)

for these complaints has not been corroborated and may be the result of other variables including normal variations in seasonal weather events. CMS is working cooperatively with the State of Alaska Department of Natural Resources to monitor the water levels in these ponds to accurately determine what if any impact occurs to neighboring lakes. CMS CUP application maintains a setback from the ponds for both the storage of materials and monofill materials. Proposed activities related to the recycle facility and monofill will not require any alterations to the ponds or aquifer. The ponds are not included in the area requested for CUP.

Maddox & Associates was hired to perform an independent review of the site hydrology and leachate concerns raised with the proposed CMS Monofill. Maddox & Associates is a nationally recognized professional hydrogeologist with experience evaluating contaminate potential in over 50 sanitary landfills in the US and Canada. Mr. Maddox looked at everything from rainwater infiltration through the monofill, potential leachate, ground water movement and potential worst case scenarios. The Maddox report and associated findings are attached. In summary Mr. Maddox found that *"the construction and operation of the proposed monofill will not present a threat to groundwater beneath the site, nor down-gradient of the site."*

A previous report by the National Demolition Association, entitled "Demolition Contractors Manage and Dispose of Waste Responsibly" confirms Mr. Maddox's findings. This report is attached and in summary finds, "For years, these facilities have accepted construction/demolition wastes and, when managed properly, pose no significant threat to the environment." "These findings support National Demolition Association's conclusion that properly designed, well maintained and operated demolition waste landfills are the most economical and environmentally sound method to manage that portion of the demolition industry's waste which cannot economically be recycled." The proposed CMS Monofill will be the first in Alaska to meet the National Demolition Association guideline for prudent, environmentally responsible operations.

To further insure the protection of the Groundwater CMS has installed monitoring wells around the site. Water level data is being shared with Alaska Department of Natural Resources for regional study of ground water table elevations.

The site has been previously completely stripped of trees reducing any potential animal habitat issues. C&D material is considered inert and non-putrescent, so it does not attract animals or birds. The CRS facility in Anchorage has processed C&D materials since 2009 with no animal attraction issues to any of the materials handled or processed.

Matanuska - Susitna Borough
Development Services

MAY 1 4 2014

Received

Odors and smells are often cited as complaints with landfills. This is often associated with putrescent rotting waste in a municipal landfill. Putrescent waste is prohibited from being disposed of in the CMS Monofill eliminating this concern. The other cited smell is hydrogen sulfide, rotten egg smells, related to gypsum wall board disposal. Gypsum is a component of the C&D waste stream that is removed for recycling. Gypsum is often ground and used as a soil amendment in farming. The removal of gypsum from the waste at CRS and the cold climate in Alaska greatly reduces the probability of any hydrogen sulfide release at the CMS site.

The Matanuska Valley has large tracts of agriculture land and the application of manure and other fertilizers creates similar odors to those complained about around landfills. Open burning and wood stoves in the Matanuska Valley can also create unpleasant odors. The CMS Monofill will not produce these types of odors and gases due to the waste material composition, material processing and operations plan.

Attached are multiple letters from neighbors to existing CRS facilities that confirms we have had no issues with odors, blowing debris or animals at our existing facilities.

Alaska Department of Environmental Conservation (ADEC) reviewed the CMS Monofill Permit application for this site and has approved the permit conditioned upon receipt of the MSB CUP.

Fire Risk

A concern exists over landfill fires. Modern landfills are designed with smaller cells of material surrounded in a fire break material. This reduces the risk a large uncontrolled fires. The CMS Monofill is designed in this manner with soil material between cells creating a fire break.

The most important part to eliminating landfill fires is proper management of how and what material is placed within the fill. Properly compacted waste reduces the potential for fires. Unlike the waste placed into most landfills or monofills, the shredded residual waste which will be placed into the CMS Monofill can be well compacted. Compaction verification testing has been performed and confirmed by Northern Geotechnical Engineering, Inc. (See attached)

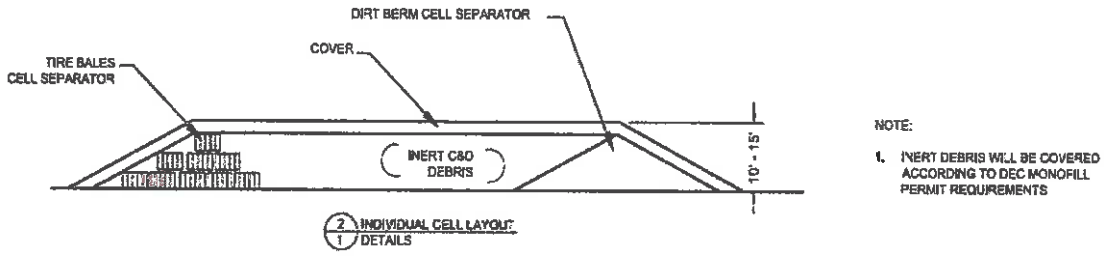
Proper management of what material is dumped in the monofill will prevent fires attributed to burning or smoldering material disposal. The CMS operations plan eliminates the risk of these hazards due to the inspection and processing of materials prior to disposal. This processing prevents typical fire starters such as chemicals, burning debris, organic debris etc. from being placed in the CMS Monofill.

If a fire were to occur at the monofill the Operations Plan includes onsite equipment and water to fight any fire. Hose and pumps will be available on site to pump water from the ponds in an emergency. Water tankers are available for dust control and fire response.

Blowing debris

Proper operations are required to prevent putative materials from leaving the site. CMS standard operation procedures reduce or eliminate the risk of blowing debris leaving the site.

Waste materials are placed within the 15' tall cell berms (See Sheet 1 Individual Cell Typical Section Drawing Above and attached). These berms are constructed prior to waste placement and form the first line of defense to loose windblown debris.



The use of a large sheeps foot landfill compactor to place and immediately compact the waste in the cell is the next method to prevent loose and blowing debris. This compactor has specially designed wheels with hundreds of pointed "sheeps foot" that help break down and lock the material together, chopping and binding the waste with the compactor wheels. This compaction densifies the material further reducing the probability of any material being loose. Regularly covering the waste with soil further prevents blowing debris.

Landfill Compactor

A remote weather station will be placed on site to monitor wind and temperature conditions. This information will be remotely available to managers and operators. When sustained wind conditions on site exceed 20mph, waste will not be unloaded without secondary containment in place.

Secondary containment involves the use of portable catch fences up to 15' tall and of variable lengths. These fences are moveable around site and can be placed near the area of operations. Catch fences are used both to slow the wind

down and to catch blown debris downwind. The MSB recently purchased these portable catch fences for use at the Central Landfill.

Portable "Catch" Fences at MSW Landfill

It is important to note that the MSB has an existing ordinance in place that can be acted upon by Code Compliance if debris was found to leave the site.

The CRS facility in Anchorage where these same materials are processed and recycled has not had any complaints or issues in the last 3 years of operation over blowing debris. See the attached letters from neighbors of CRS that confirm no issues with blown debris.

Standard operations and available secondary containment will prevent blown debris and eliminate this concern.

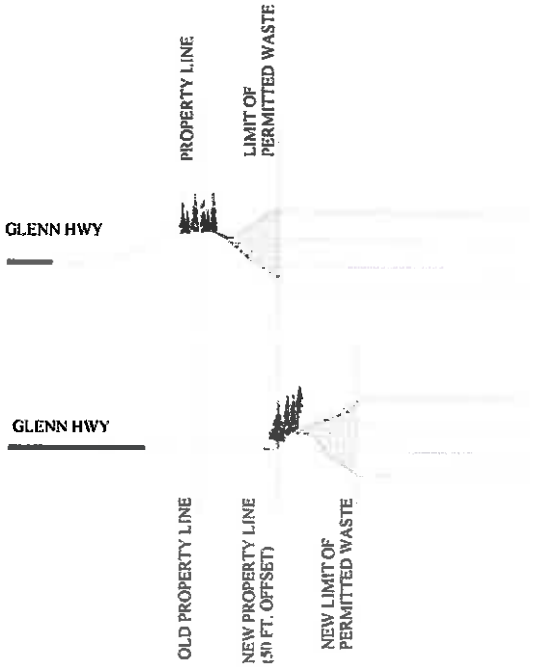
Permit: *Application for a Conditional Use Permit- MSB 17.60*
Applicant: *Central Monofill Services*
Date Submitted: *January 15, 2014*

Visual screening and ROW

The recycle facility and monofill have been designed to be out of view from the public Right of Way (ROW) which is a 17.60 requirement for the CUP. The only public ROW adjacent the monofill is the Glenn Highway. The visual screening and berms are in place due to the Existing Material Extraction use on site. CMS will comply with the 17.60.110 screening requirements

Construction of the monofill requires retaining berms creating the cell walls to place the monofill material inside of. These berms have to be constructed prior to waste placement in order to contain the waste materials. This berm will also screen the monofill from view. Areas along the ROW where the trees maybe thin or the final monofill height may near the height of the trees will be visually screened by these new cell berms. See the attached drawings for details of these berms and screening.

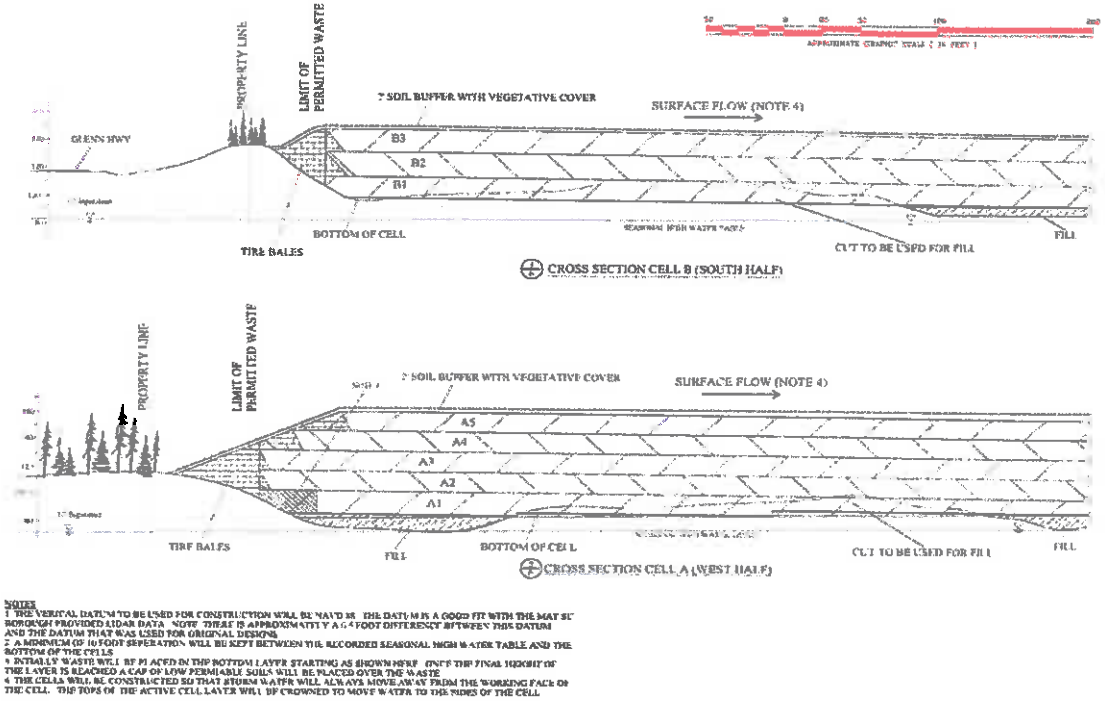
View of Right of Way from Road and existing berms and trees to screen monofill. Final height near tree tops.



Right of Way Screening Plan

Permit: *Application for a Conditional Use Permit- MSB 17.60*
Applicant: *Central Monofill Services*
Date Submitted: *January 15, 2014*

Since 1989 The Alaska Department of Transportation (ADOT) has discussed several concepts to improve the Glenn Hwy along the property. This Highway project may require ADOT to condemn some of the CMS property including part of the existing berm. In the event the state removed some of the existing visual screening CMS will maintain a continuous solid fence or earthen berm no less than 8' in height in compliance with MSB 17.60.110



NOTES
1 THE VERTICAL DATUM TO BE USED FOR CONSTRUCTION WILL BE NAVD 88. THIS DATUM IS A GOOD FIT WITH THE MAT SU BOROUGH PROVIDED LIDAR DATA. NOTE: THERE IS APPROXIMATELY A 6.4 FOOT DIFFERENCE BETWEEN THIS DATUM AND THE DATUM THAT WAS USED FOR ORIGINAL DESIGN.
2 A MINIMUM OF 10 FOOT SEPERATION WILL BE KEPT BETWEEN THE RECORDED SEASONAL HIGH WATER TABLE AND THE BOTTOM OF THE CELLS
3 INITIALLY WASTE WILL BE PLACED IN THE BOTTOM LAYER STARTING AS SHOWN HERE. ONCE THE FINAL HEIGHT OF THE LAYER IS REACHED A CAP OF LOW PERMIABLE SOILS WILL BE PLACED OVER THE WASTE
4 THE CELLS WILL BE CONSTRUCTED SO THAT STORM WATER WILL ALWAYS MOVE AWAY FROM THE WORKING FACE OF THE CELL. THE TOPS OF THE ACTIVE CELL LAYER WILL BE CROWNED TO MOVE WATER TO THE SIDES OF THE CELL

Typical Property Cross Section at ROW

From inside the CMS property, only one house is visible. This house is on a natural rise over a quarter mile away with other gravel pits in between. The adjoining residential lots are screened from view of the property by trees.

View from inside property looking South West toward residence. The final height of the monofill will not exceed the height of the existing tree line.

All MSB 17.60 Public ROW screening requirements are met with this CUP application.

Health and Safety Review

Beyond the safety of the groundwater supply, other health and safety factors were reviewed. Health and safety issues would mainly be related to the delivery, acceptance and disposal of unknown or Hazardous Wastes. CMS and CRS have specific policies, further outlined in the Operations Plan, to prevent these materials from being delivered to the facility. Hazardous materials pose a significant risk to employees in the recycling and Demolition process. Federal regulations must be followed to protect the workers during handling of these materials. If C&D is handled properly, per Federal regulations, in the demolition and recycling process there will not be any possible exposure to the public.

C&D debris delivered to the facility will go through the CRS acceptance process outlined in the Operations Plan. This process will prevent Hazardous Wastes from being delivered and if they were, identifies how they will be properly handled to prevent any exposure.

Per the ADEC permit municipal and household waste will not be accepted at the facility. These materials could contain known and unknown hazardous wastes potentially dangerous to the public. By not accepting these materials this risk is eliminated. Only known haulers and previously approved contractors will be allowed to bring material to the facility. This is controlled by gates and onsite personnel that will inspect all loads delivered to the facility. This is further monitored via camera security systems. Loads hauled into the facility that have not been previously inspected by CRS personnel will be dumped onto a lined pad for inspection. This inspection pad will consist of a 50'x100', 30 Mil Pit Liner capped with 2' of soil. Loads dumped on the inspection pad will be inspected for suspect or prohibited materials. Loads found to be clean will be placed into the monofill or trucks for back hauling to the CRS Anchorage Recycle facility. This inspection pad will reduce the risk of contamination due to improper dumping. Should something prohibited be dumped on the pad it can be cleaned up without risk of subsurface contamination. This inspection pad will be near the working area of the landfill and relocated as the cells and working area move within the monofill.

It has been argued that C&D debris is hazardous because construction materials may contain chemicals that are hazardous. An example is carpet. Carpet may contain formaldehyde or other hazardous chemicals. It is argued the carpet must therefore be hazardous. These hazardous chemicals can be in the carpet or other building materials in your house where children may play and is considered safe for human exposure. These materials typically do not change chemical composition when buried in a monofill. These C&D materials do not suddenly become hazardous wastes after demolition. Hazardous wastes in a building or home are required by the EPA to be identified and removed from the structure prior to demolition. Common items removed are mercury switches that are found in thermostats, mercury containing fluorescent light bulbs and radioactive exit signs. Proof of this removal is required prior to delivery of materials to CRS and CRS employees are trained to look for suspect materials. Suspect materials delivered to CRS are tested

and, if found, removed from the waste stream, and the client charged for the proper disposal.

Some building materials have paint or other coatings on them. Suspect material will be tested in accordance with regulatory required test methods to identify hazardous materials content, if any. Should lead based paint be found on debris, a Toxicity Characteristic Leaching Procedure (TCLP) analysis of the waste stream will be performed as required by the EPA. Only painted materials determined to be non-hazardous in accordance with EPA regulations will be accepted.

Asbestos will be accepted for disposal at the CMS Monofill in accordance with all applicable federal and state regulations for packaging, labeling, transport handling and disposal. Asbestos containing materials (ACM) are categorized into two types, Regulated (RACM) and Non-Regulated (Non-RACM). Regulated asbestos waste will be placed only in a pre-designated cell designed and maintained for this sole purpose. This cell is permanently fenced off from the other monofill cells, and the waste will be covered by non-organic soils on a daily basis. A copy of the RACM asbestos waste manifests must be provided to the regulatory agency within ninety days of disposal.

When handled properly per Federal regulations, asbestos wastes do not pose an environmental or health risk. Asbestos fibers do not dissolve, are a heavy mineral fiber and do not transport in groundwater and therefore pose no risk to the groundwater supply. The potentially friable asbestos waste accepted at the site must be properly packaged to ensure no airborne release, and in accordance with ADEC requirements, the packaged waste is covered daily.

Dissolved metals have created leachate issues in old landfills where both ferrous and non-ferrous metals were buried as a standard part of the C&D waste stream. Today, these metals, both Ferrous and Non-Ferrous are a valuable commodity that is actively removed from the waste stream and recycled. Extremely low percentages of any metals will be left in the waste which will be placed in the CMS Monofill which eliminates the concern over dissolved metals.

Safety concerns over trucks and traffic are no greater than the current use of the site for gravel extraction. The entrance directly off the Glenn highway keeps truck traffic out of residential areas or other side streets.

Central Recycling Services

CMS will contract with Alaskan owned and operated Central Recycling Services (CRS) to operate the proposed Recycle Facility and inert debris monofill. CRS has operated a monofill for CMS in Salcha, AK since summer of 2012.

Salcha Canaday Homestead C&D Monofill;
Salcha, Alaska
Owner: Central Monofill Services, Inc.

CRS, one of the Central Companies, is a waste management company that specializes in the recycling of C&D materials. CRS has operated Alaska's only mixed C&D recycling facility in Anchorage since 2009. CRS has other recycle operations in Fairbanks and Prudhoe Bay.

The CRS Anchorage Facility operates industrial sized recycling equipment capable of processing large volumes of material. A large shredder, crusher, screens, magnets and sort lines make up the main equipment used to process the C&D material. Stockpiles of unprocessed C&D, residual waste material and recyclable material are often at this site. This facility is located on the bank of Ship Creek, within 1000' of a fish hatchery, 200' from a bike trail and adjoined on three sides by other business with offices steps away from the recycle facility. CRS has never had complaints of smells, flying debris, dust, trash, animals etc. that are often cited as concerns of the subject CUP. The close proximity to neighbors at the Anchorage facility, and large piles of C&D material would make the probability of nuisance issues the highest at the CRS facility. See attached letters from neighbors to existing operational CRS facilities that support this claim. Monitoring wells on CRS Anchorage site have been tested for water quality and nothing has been measured in the 4 years of operation. Again the highest likelihood of any measurable contamination would be at this facility where the C&D is not covered during processing.

CRS generally recycles over 75% of waste received and has pioneered the manufacture and use of several recycled content products in Alaska. Pioneered products include Tire Bales and Recycled Glass Aggregate (RGA).

CRS's record of success in protecting its workers, neighbors and the environment while recycling and processing C&D makes CMS confident in being able to operate this new facility in the MSB while ensuring the safety, health and welfare of borough residents.

Property Values

It has been argued that monofills will lower surrounding property values. Property value data does not support this either locally or nationally. Recent data used for the Alaska Demolition CUP renewal with the City of Palmer[5] shows an increase in property values around their C&D Monofill in Palmer over the last several years. This site located less than 2 miles from the Proposed CMS Monofill is directly adjacent to the Majestic Hills subdivision. During the public testimony and public comment period for this extension no issues were raised with property values around that site. The data provided by Alaska Demolition in their CUP shows a minor increase over the last three years. A local independent Real Estate broker Laura Hamilton was contacted in regards to property values around Landfills. Mrs. Hamilton found that "Based on the review of sales data the overall value of the properties located around the Alaska Demolition Monofill, MSB Landfill and Former Chugiak Landfill have increased at the same rate as properties further away." A review of property values adjacent to the MSB Central Landfill verify that property values have increased over the life of the Landfill. Spreadsheets with property values are attached.

It is important to remember that the CMS property is currently an approved existing mineral extraction site. Per the Alaska Property Disclosure form a seller has to disclose if their property is within 1 mile of a gravel pit or fill site. Item23. "*Are you aware of a waste disposal site or a gravel pit within a one-mile radius of the property*?" Anyone within 1 mile of this property is already required to disclose this property as a gravel pit or fill site not drawing a distinction between the two.

Mrs. Hamilton's states "In reviewing property disclosure forms, another thing I found interesting is that sellers adjacent to the Alaska Demolition Monofill in several cases did not acknowledge there is a site in these areas, Page 5 of the Alaska Property Disclosure, asks if you are aware of any waste disposal site or gravel pit within one mile radius of the property. In some cases it was marked No, and other did not mark it at all. For sellers to not be aware of an adjacent gravel pit or Waste site would indicate that these are very unobtrusive operations that would not have adverse impact on property values."

Mrs. Hamilton's review concludes "Based on this I would not expect your proposed facility to impact surrounding property values particularly not 10% or more."

Many closed and reclaimed Landfills become sought after properties when they are reclaimed into parks or other recreational space. In Anchorage, multiple public facilities are built upon closed Municipal landfills. The Loretta French Equestrian Center, Merrill Field Airport and De La Vega Ball Fields are a few examples. Portions of the Alaska Regional Hospital are built directly on top of the old Anchorage Municipal Landfill.

---

[5] Supplement to Conditional Use Application, Submitted by Alaska Demolition LLC, Concerning the Palmer Reclamation Site (aka Rebarcheck Pit)

These Municipal Landfills were typically unlined and accepted all municipal wastes. Long term monitoring of these sites has identified minimal or no environmental or public health issues.

Total Permitted Acreage

CMS purchased both Lot C010 and Lot B006 in December of 2012. The two properties are adjacent, combining to a total of 118 acres. These two properties share one single access from the South Glenn Highway. There are three industrial ponds located on the northern half of the property which cover 66 of the acres. The industrial ponds do not have any relevance with respect to the proposed monofill or recycle facility. Please refer to the Site Plans, Sheet 1, showing the separate location of the monofill in respect to the separate location of the three industrial ponds.

Of the remaining 52 acres, the monofill footprint is proposed to be 35.5 acres with 16.5 acres used for recycling operations. *Recycle Facility, Material Reuse Business or Monofill* are generally categorized by the Matanuska-Susitna Borough Specification 17.60 definition as a "Junk Yard". The CUP is needed for 52 acres of the property. As a recycling company, building materials may be stored or processed outside of the footprint of the monofill. A scale house, maintenance shop and other support facilities will be needed to support the monofill and recycling operations. These facilities will be placed outside the 35.5 acre footprint of the monofill. See the attached Sheet 1 Conditional Use Permit Site Plan

Inert Debris Monofill Construction and Development

Site Topography

Due to the mineral extraction which occurred by the previous land owner, both lots have very similar topography. This topography, in essence, is a large bowl. The perimeter of this property has elevated sides sloping downward into the base (or the bottom) of the topographic bowl. As this bowl exists currently, the property's topography is ideal for the construction of a monofill. Lot B006 is located directly south of Lot C010, as shown on the attached Site Plans. The monofill is proposed to be constructed on the majority of Lot B006 and the southern part of Lot C010, as indicated on the Existing Conditions Sheet 1.

Lot C010 contains the three large industrial ponds (located at an average elevation of 77 feet ASL on the northern half of the lot). Again, these industrial ponds do not have any relevance with respect to the proposed monofill. The proposed monofill footprint is not adjacent to these industrial ponds, and does not touch or overlap any part of the industrial ponds. Please refer to the attached Site Plans showing the separate location of the monofill in respect to the separate location of the three industrial ponds. These industrial ponds also have a minimum 25' setback buffer located around the entire perimeters of each pond for any activity and a minimum 100' setback from the monofill. .

The surrounding west, south and east sides of these properties are naturally occurring elevated hills creating the west, south and east sides of the proposed monofill. The north side of the topographic bowl has the lowest elevation. By using the existing topography, this lessens the amount of constructed/man-made retaining walls needed for the site. CRS has been working with engineers to design and construct the northern side of the monofill. Within the southernmost boundary of Lot B006, retaining walls may also be used in the small saddle within the existing south-eastern topography. By elevating the low laying saddle in the south-east topography, this will bring the height of the southern cells of the monofill to the original topographic elevation of the site.

These naturally occurring hills will also create a visual buffer from the Glenn Highway. The existing driveway enters the site on the east side of Lot C010 from the Glenn Highway, and steadily slopes down towards the southern center area of Lot C010. There will be no direct line of vision of the monofill from the South Glenn Highway entrance or any other public ROW.

The entrance to these two lots is gated. The truck scale and scale house/field office will be located behind the gate to regulate trucks entering and exiting the site. This entrance will also separate traffic from the monofill and recycling operations. The monofill will not be open to the public.

Approximately a seven acre portion of the property north of the entrance, southeast of the ponds, will be leveled for a future reclaimed and salvaged material Sales Yard, equipment storage and a potential warehouse or shop building area. A future equipment maintenance shop building is also proposed to be constructed within this area.
The vegetation that is remaining on site is the forest located along the top of the mined banks and helps create a visual barrier between the public and the CUP activities. The existing trees will be left in place and used as a visual and noise buffer. Please see the Site Plan for further reference.

Excavation required for the monofill is limited to shaping the existing terrain. No excavation is required within 4' of the water table.

Monofill Construction

Base Construction

The ADEC requires the base of the monofill to be a minimum 10' above the water table. The Maddox & Associates report confirms the 10' requirement as sufficient to protect the water table. The existing 7 monitoring wells on site have been measured over the last year to determine the seasonal elevation of the water table. These measured ground water elevations were used to determine the minimum elevation of the bottom of the monofill. More than 70% of the existing monofill footprint is already in excess of 10' above the seasonal ground water table. Those areas with insufficient separation from ground water will be filled with onsite earthen materials to obtain a minimum separation of 10'. On site overburden and waste soils left over from mining activities will be placed and compacted to design grades prior to monofill waste placement. Materials with low percolation rate are intended for use under the monofill. Moisture percolation testing was performed by Environmental Management Inc. on the various on-site soils which could be used for the base of the monofill. These percolation test results were used in the Maddox & Associates evaluation of the site. Percolation test reports, material reports and ground water map are attached.

Material Containment

The proposed cell walls and slopes will be made from soil or recycled tires in the form of tire bales. (See Individual Cell Typical Section Drawing Below) CRS has been collecting tires from the community and locally manufacturing tire bales since 2011. Tire bales are made from 70 to 100 used tires pressed into desk sized cubes (about 5' x 3' x 3') and banded with stainless steel wire to create a light weight structural building block. These bales are designed and engineered to be stacked, as shown on The tire bales allow slopes to be steepened

Tire Bales

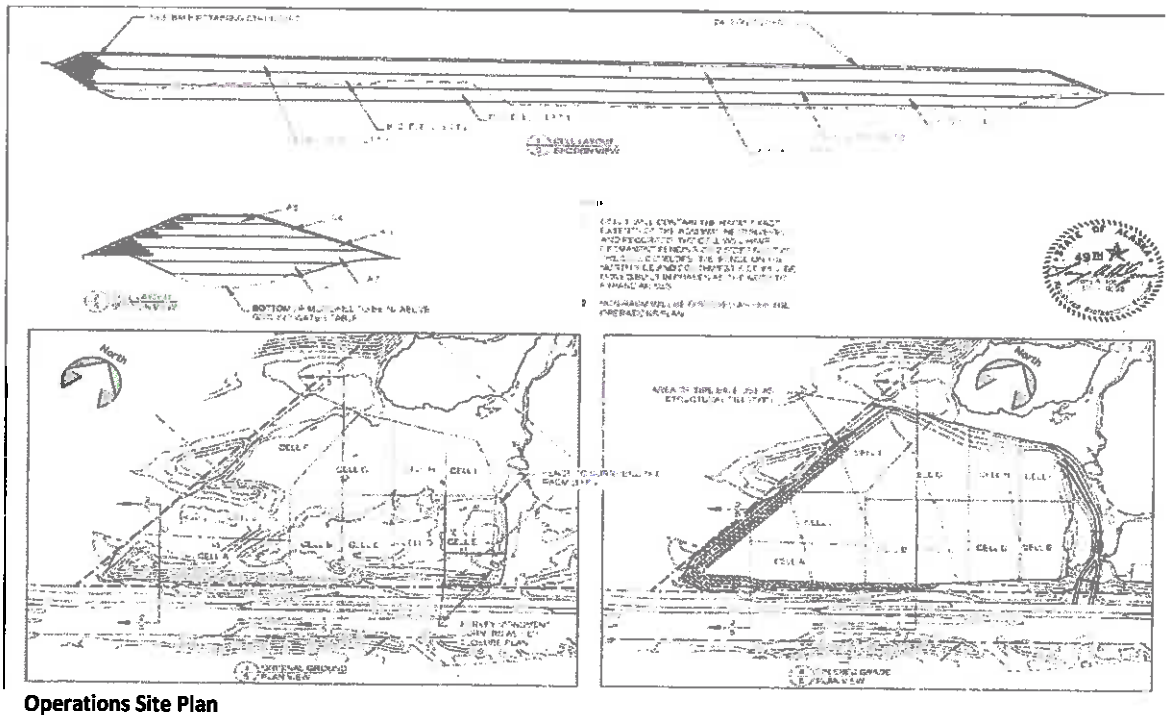
along the outside of the monofill. To lessen the visual impact of tire bales, the outer face of the tire bale wall will be covered with soil and exterior monofill slopes vegetated.

Material Compaction

Placement of material within the cells is performed with large landfill compactors which will compact the material and reduce loose debris. Each load is compacted by a sheep's foot compactor. This compactor will compact the debris the day it arrives on site. RACM loads delivered to the monofill are packaged in sealed leak proof containers, placed within the designated cell. These materials are not compacted by equipment to insure the integrity of the packaging.

Sequence of Fill

Filling of cells will start at the southernmost part of the property and advance to the north. This inert debris placement process will begin on the first lift in Cell A. Each cell is proposed to be about 125 foot wide (see attached Sheet 5 Operations Plan and Sheet 6 Cross Sections). Each cell will have sub-cells created within. These cells will be wide enough to allow trucks to easily maneuver within the cell and place their loads in the correct locations. The trucks will drive into the operational cell, turn around, and backup into the directed area, to then place its material. As the trucks leave each load of material, a landfill compactor, or dozer, will spread the material into two foot deep lifts and compact



Operations Site Plan

Shredded Residual Material

the placed debris within the operating cell. This process will continue until the layers within the cell reach a depth of 15 feet. The placement of inert material into this monofill site is proposed to be over a period of approximately thirty years.

CRS has performed density testing on the shredded residual material and found it highly compactable. Unlike traditional landfills and Monofills, the shredded residual is a consistently sized material that upon compaction reached near soil densities. The consistency of this material will reduce long term differential settlement often seen in monofills. Differential settlement occurs when large and inconsistently sized materials are buried that doesn't compact well and create large underground voids that slowly fill over time and creat movement in the fill. This movement can result in the final surface above a fill to settle. The CMS Monofill built primarily with shredded residual material and properly compacted will result in a stable fill with a smooth top suitable for agriculture or sports fields. Northern Geotechnical Engineering, Inc.'s compaction summaries are attached.

Monofill Cover/Closure

Material excavated from adjoining cells that will be under development will be excavated, hauled, and placed as the cover material for the operational cell prior to starting the next cell up. There will be a one foot lift of soil separation between each Cell to create multiple fire barriers throughout the monofill. This surface will be graded to drain in order to prevent surface ponding and reduce infiltration. Earth from adjoining cells will be excavated and used for the construction of access roads and some cover material within the monofill.

In accordance with the ADEC permit, the cells within the monofill will be capped as required either weekly or when cells are full, as shown in the Operations Plan. This surface will be graded to drain in order to prevent surface ponding and reduce infiltration. Per EPA and OSHA regulation, RACM and Non-RACM will be covered on a daily basis. Other materials deposited into the monofill are placed within the cells and will be covered intermittently, however not necessarily daily. Sides of the cells are constructed prior to filling each cell, which create barriers on two or three sides, helping block the wind and contain the material. These cell walls are shown on Sheet 1 Individual Cells Typical Sections.

Once areas/cells of the monofill are filled to final height, native soil, strippings, compost, etc. will be spread over the top and slopes of the cell for a minimum of two feet. This final

surface will be graded to drain in order to prevent surface ponding and reduce infiltration. This cap for the monofill will be seeded and will allow the establishment of vegetation over the surface to occur. All drainage will flow away from the working face of the monofill and a minimum of 2% grade will be required.

The ADEC permit requires the owner to provide bonding or other financial assurance to cover the cost of monofill closure. The ADEC has a predetermined method for calculating the amount required for the bond or other financial assurance to make sure it is enough to cover all closure costs. CMS has met this obligation as part of the ADEC permit. CMS also has sufficient Environmental and Pollution Insurance to cover this project.

Summary

There is a need in the MSB for C&D recycling and this CUP will facilitate the development of C&D recycling and the manufacture of recycled content materials in the MSB. This expansion of industry will bring new materials, options and jobs to the MSB. This can be done without sacrificing the health and safety of the public or environment. The design and operations of the facility will protect our workers, the public and the environment. The materials brought to this facility and their handling is regulated by EPA and OSHA and the Monofill itself regulated by the ADEC to protect the health, safety, convenience and welfare of the public.

Per the MSB Comprehensive Plans these old gravel pits can be used as Industrial property and the proposed industrial use has an added benefit of eventually creating green space.

The requested CUP should be issued as it meets or exceeds all of the MSB 17.60 Requirements.

MSB 17.60 Requirements

1. Is the conditional use compatible with and will it preserves or not materially detract from the value, character and integrity of the surrounding area?

2. Will the granting of the conditional use permit be harmful to the public health, safety, convenience and welfare?

Response to Requirements 1 & 2

The proposed Conditional Use is compatible with the surrounding uses. The existing use of the site is for Earth Materials Extraction, an Industrial use. Large scale gravel extraction operations or commercial operations account for 76% of the surrounding properties. Low density residential only accounts for 24% of the remaining surrounding properties. The

Recycle facility component of the CUP is a light industrial use that would be buffered by the Monofill. The use of old gravel pits for industrial use is supported by the comprehensive plans. Granting of this CUP will allow filling and reclamation of areas of the old gravel pit turning them into green space that could be used for parks or agriculture.
The proposed Conditional Use will not be harmful to the public health, safety, convenience or welfare. The inspection, handling and processing, of the materials insures that regulatory restricted materials are not delivered or disposed of at the proposed facility. Only ADEC approved "inert waste" will be allowed for disposal at this facility. Recycling and processing of the waste such as at the CRS recycle facility in Anchorage removes other materials that could cause odors. Odors related to neighboring farming operations such as land application of manure and fertilizers create more odors than will ever emanate from this facility.

Operations at the facility will be screened from view as required by code. The existing topography will screen most operations. The existing mineral extraction use requires the same screening needed for a Junk Yard CUP. As areas of the site are filled above the existing topography the required cell construction will create additional screening. Cells of no greater than 15' high will be built to contain the waste materials. These cells have soil covered earthen berms around the perimeter to contain the waste and additional provide the required screening. See the Attached drawings.

Best Management Practices to include: not unloading debris during high wind events, regular/timely compaction with a sheeps foot compactor, weekly covering of waste with soil, construction of 15' tall cell berms and the use of portable catch fences reduce the likelihood of any windblown debris from leaving the site. Employees will regularly patrol the perimeter of the property to clean up any loose debris if any.

Noise from the site will not exceed current Borough Code and will be similar or less than what is currently allowed or heard from the existing earth materials extraction operations.

Traffic to and from the site will not exceed current Borough Code. Traffic will enter the site from the Glenn highway and will not create any issues of mixing commercial traffic with residential.

According to the attached Maddox & Associates report the Monofill can be constructed and operated without an impact to groundwater.

If the site is not visible to the public, nothing blows off site, no odors emanate from the property, does not exceed code requirements for sound and does not pollute the ground water then the requirements of 17.60 1 and 2 are met.

Monofill design and operations are permitted by the Alaska Department of Environmental Conservation (ADEC). Again, the ADEC permit requirements protect public health, safety and welfare. The proposed monofill design has been submitted to ADEC for review and

approval. ADEC has approved the proposed monofill design pending receipt of the MSB CUP. The proposed uses will not increase activities beyond what the property is already permitted for, and therefore, will not negatively impact the public and/or their convenience.

As this property is private property, signage will be posted at all entrances to the property including the main entrance of the property on Lot C010 informing the public to take caution of not entering the site unless authorized and/or accompanied by authorized personnel. This access point will prevent unsolicited visitors to trespass onsite (pedestrians/target practice/off-road vehicle usage) and away from any site activities.

There is also no concern of wildlife, or domestic animals, being attracted to the inert debris and the monofill operations. Since there will be no putrescible waste allowed (or disposed of) in the monofill, there will be no animals attracted to the site. The lack of putrescible waste eliminates odors and/or disease issues on or off site.

The recent renewal of the Alaska Demolition CUP for the Rebarchek Pit is further evidence a C&D Monofill in the MSB can be operated safely within the requirements of 17.60. During the public testimony for this CUP only one person testified. The testimony said although things had operated well they had issues with odors from the site and thought the weeds on the perimeter berm were unsightly. Nobody testified or made complaint about property values, incompatibilities, noise debris or other issues. The CMS Monofill will not have the same odor issues as the AK Demolition Monofill as materials are inspected processed and handled differently to remove the offending materials prior to delivery to the CMS site. If after 10 years of operation the AK Demolition Monofill only had one person speak at the Public Hearing it is a fair assumption the CMS Monofill can be operated as well or better. The CMS operation has more extensive testing, inspection, processing, handling and monitoring than either of the other two C&D Monofill's located within 2 miles of the subject site.

It should be found that the CMS CUP can meet the requirements of 17.60

3. Are sufficient setbacks, lot areas, buffers and other safeguards being provided?

Currently on the existing site, there are no permanent or semi-permanent buildings; therefore there are no current setbacks from these buildings. Potential future structures will be placed more than 30 feet from the current Right-Of-Way and therefore setback requirements will not be an issue for these structures.

The ADEC regulations require that waste which is to be placed within the monofill be kept at a minimum of 50' from all property boundaries. Please see the Site Plan for the proposed location of the monofill and for the potential locations of any future structures.

CRS has implemented a minimum 25' setback from the industrial ponds on site. This setback states that no material will be placed or stockpiled within this 25' boundary between the industrial ponds and the rest of the useable property areas. No waste will be placed within 100' of the industrial ponds. This implementation not only reassures the public that the industrial ponds will not be affected by the monofill and its recycle operations, but this also helps CRS protect the industrial ponds. This 25' / 100' setback is shown on the attached Site Plan.

The utilization of the natural vegetation and naturally occurring hills of the property will be employed as both visual and noise buffers. The usage of the existing site topography will allow Central Recycling Services to create a natural property/site boundary without the use of extensive fencing. Central Recycling Services will place the inert debris into the 35 acre monofill area without disrupting the current neighboring lands' ecosystems, both agricultural and natural occurring bio-networks.

The cell walls, as show in Sheet 3, the natural topography of the surrounding hills, and litter fences, reduce the possibility of dust and debris from being able to leave the site. The nearest home to the Monofill site is 500 feet with a nearly 300 foot buffer of trees.

The CMS CUP meets the setback requirements of 17.60.

4. Does the conditional use fulfill all other requirements of MSB Chapter 17.60 pertaining to the conditional use in this section?

Yes, this conditional use does fulfill all other requirements of MSB Chapter 17.60 regarding the conditional use.

Supplemental Information Requested by Staff

1. ***Number of Employees proposed to work on largest work shift:***

Three (3) employees will be used for normal monofill operations and up to thirty (30) for periodic accessory operations.

2. ***Hours of Operation***

This site will operate on a seasonal schedule. During the months from May through September, the operational hours will be from 7am to 7pm, Monday through Saturday. Throughout the months of October to April, the standard operational hours will be from 8am to 5pm, Monday through Saturday on an as needed basis.

3. ***Noise Mitigation Measures***

The prior and existing use, on this property is Mineral Extraction. Equipment associated with Mineral Extraction is generally similar to the equipment required for operating a monofill. There will not be an increase in the amount of equipment or truck traffic compared to the existing use and as such noise levels will not be greater than the existing permitted use. . In an effort to further reduce noise, monofill operating equipment will be fitted with white noise back up alarms that reduce sound associated with beeping back up alarms. The existing surrounding topography and vegetated buffer also assist to mitigate noise from the site. The proposed operations will comply with MSB existing sound ordinances.

4. ***How will contaminated material be handled and disposed of at this site?***

As previously mentioned, all material, including the shredded residual material, will be sorted by the operator, at Central Recycling Services either at the site or before the inert material is brought to the monofill site. During the inspection and sorting procedures, all material is thoroughly screened before it is allowed to be disposed of on site. Therefore, it will not be necessary to clean up any prohibited or unauthorized waste since thorough screening procedures will eliminate the possibility of hazardous or unauthorized waste being placed into the monofill site.

The recycle facility at CRS abides by all federal, state or local regulations and permit conditions regarding inert debris inspections, handling, placement and sorting of material. These same procedures will be applied to any materials delivered to the monofill.

In the unlikely event of a contaminated material brought to the monofill, both Central Monofill Services and Central Recycling Services have trained individuals receiving the waste who can identify potential unauthorized materials. All waste delivered directly to the monofill is first placed within a lined area and inspected. Questionable materials are identified, tested and properly segregated from the waste stream. CMS and CRS will have authority to contact an environmental remediation firm of its choice and request the contaminated material be disposed of quickly and properly. The cost of this cleanup operation is charged to the owner of the material.

5. ***Total square footage or acreage of this property:*** 118 acres total

6. ***Total square footage or acreage for this use on this site:*** 52 acres for the recycle facility and monofill. The monofill is 35.5 acres within the 52

7. ***Are there other existing or proposed uses on this site or will this operation be the sole use of the property?***

This site is permitted for mineral extraction. With issuance of this CUP permit, mineral extraction would be a secondary or accessorial use, to the monofill and recycling operations.

8. ***Use(s) of any proposed building(s) associated with this operation:***

The proposed future buildings associated with this monofill, recycling operations and equipment maintenance on the site may include a warehouse, shop, field office / scale house. The proposed locations can be seen on the attached Site Plan Sheet 2.

In addition to proposed future buildings associated with the recycling operations on site, laydown and storage areas are also proposed. A laydown area is a location on site that is used to store equipment, material, etc. for a certain amount of time.

A laydown area is different than a storage area. A storage area has a purpose to allow items to be left with no timeline as to when the items will leave the site. A laydown area usually accumulates items that will be used within the near future. These items placed in a laydown area usually have an identified purpose and will be needed in another location sooner than later, therefore, these items typically do not stay in the laydown area for long periods of time.

The materials that are typically placed in the laydown areas are frequently salvaged materials or materials that are needed to be processed. Currently, many customers purchase reusable materials from CRS' salvage laydown yards. These materials range from usable windows taken out of a local demolition project to new pieces of HDPE pipe that were extra pieces and not needed on a local utility project.

9. ***Copy of Hazardous Material Plan for the operation, if applicable:***

Regulated Asbestos Containing Material (RACM) waste will be accepted at the monofill site but will have to be scheduled for delivery and disposal. All waste that includes regulated asbestos-containing material (RACM) waste will be managed in a manner that prevents the release of asbestos fibers to the air or to surface water and must be disposed of in a designated cell (such as Cell E). The base of the asbestos cell will be undisturbed earth or stable fill and will be fenced from all other monofill operations. The cell is located in a manner that it will not preclude any future closeout or remedial action at the facility.

The CRS operator shall inspect each load of RACM waste to assure that the friable asbestos material is sealed in leak-proof bags or containers, labeled in accordance with 29 CFR 1910.1001(j)(4), revised as of July 1, 1998. The waste will be accompanied by a complete and accurate shipment record meeting the requirements of 18 AAC 60.

RACM Bag ready for disposal

After placement of packaged RACM in the monofill, it is required to be covered on a daily basis.

CRS will retain a copy of all records required under 18 AAC 60.450 for at least two years, and shall furnish them to the DEC upon request.

As required by regulations, CRS will maintain in the operating record of the monofill a map or diagram showing the surveyed boundaries of the asbestos waste management area, its depth, and the amount in cubic yards, of the RACM waste located there. These documents will be maintained until the monofill closure is complete and beyond.

10. ***Type of equipment to be used at this site:***

Excavator, wheel loaders, fork lifts compactors, trucks and Bulldozers.

11. ***What type of containment systems will be in place at this site?***

As mentioned in the above, soil or tire bales will be used to create cell walls for steepened slopes. Existing hills will also be used as cell walls of the monofill. Soil barriers will be used for monofill cell containment and as fire barriers throughout the monofill. All containment will meet ADEC requirements for a monofill. The attached Maddox & Associates report supports our design and the ADEC regulation that an impermeable liner is not required for this facility.

12. ***What type of non-permeable surface will be in place at this site?***

The entrance driveways and approaches to the truck scales may potentially be paved to minimize tracking and dust. This will amount to less than 1% of the surface area of the site.

As stated previously, the working face of the proposed monofill will be routinely graded and compacted to ensure water drains away from the working area and that there is no ponding. The working surfaces will be graded to ensure surface water does not enter the material placed into the monofill, and to direct the water away from the placed material.

Please see the design drawings and the Maddox & Associates report on water transmission through the monofill and findings that a non-permeable liner is not required under the monofill.

13. ***What will be the daily traffic generation for this use?***

The monofill is not open to the public. The recycle facility will have some public traffic but estimated to be low volume. The MSB levels specified in 17.61.090 "Core Area Land Use Permit" application will not be exceeded with less than 100 trips during peak and 750 total per day. Central Recycling Services Daily Trip Rate is calculated at an average of 6.97 -daily trip rate using the "Common Land Uses Chart" in the "Core Area Land Use Permit" application. Central Recycling Services is prepared for summer traffic to be heavier than winter traffic due to hours of operation, the Alaskan construction season, and weather

conditions. It is anticipated that we will reduce the truck traffic during the Alaska State Fair.

14. ***Attach a written description of the buffering that will be provided at this site to meet the standards in 17.60.110.***

See the above section on Visual Screening and Sheet 6 Cross Section of the drawings and Sheet 1 Individual Typical Section

Site Plans

Please see the attached detailed Site Plans for the requested Site Plan Items 1 through 14.

Closing/Conclusion

This CUP application meets all applicable MSB Code 17.60 requirements for a Junkyard. The proposed recycle facility and monofill meets all applicable Federal and State requirements. The design and operations plan for this facility meets or exceeds all health, safety and environmental controls required by any applicable regulatory agency. . Although not required by regulation, and expert opinion indicates no risk to the groundwater, CMS has installed monitoring wells and developed a ground water monitoring plan which will be implemented to verify compliance. . The existing site has been studied by experts, the design reviewed independently and by the ADEC, the materials going into the monofill have been tested by independent testing laboratories and a thorough operations plan developed, all to insure the health and safety of the public and environment. All other concerns that have been raised by MSB staff or the public have been reviewed and addressed.

All of the facts support that the CUP as submitted should be unconditionally approved.

REPORT SUBMITTAL

All work performed during the planning of this project, the interpretation of data collected, and the preparation of this report was done according to the accepted standards of the profession. To the best of my knowledge, all of the data presented in this report are accurate. The stated conclusions are based upon a finite amount of data available--additional data, if available, may result in modification of some of the conclusions presented herein.

Respectfully submitted,

Steve Maddox

Steve Maddox, CA PG 4814/CHG 298; AZ PG 529

EVALUATION OF PROPOSED PALMER MONOFILL WITH RESPECT TO POTENTIAL IMPACT ON GROUNDWATER

1.0 EXECUTIVE SUMMARY

Maddox & Associates, Inc. (M&A) was asked to review the plans and procedures for the construction of an inert monofill near Palmer, Alaska. The main goal was to evaluate the potential for possible contamination of the underlying aquifer by leachate that might be released from the inert materials. M&A has experience evaluating contamination potential and associated landfill problems at over 50 sanitary landfills. This work has been conducted in all of the regions of the United States and in Canada.

A Site Conceptual Model (SCM) was constructed to provide a brief, overall understanding of the proposed monofill and its relation to the underlying aquifer. A summary of the SCM indicates that it will be constructed in such a manner and will contain inert materials such that it will not pose a threat to groundwater or human health; limited infiltration by low rates of local precipitation will minimize the volume of liquid entering the inert materials; groundwater modeling indicates that, should any contaminants that pose a threat to human health enter the groundwater beneath the site, they would not travel significant distances before they began to degrade and their concentrations would be reduced to low levels (as much as 96% after one-mile).

The site is located approximately 3-miles southwesterly of Palmer, Alaska; it has been historically used as a gravel pit. The portion of the site to be used as a monofill will comprise 35.5 acres. The materials it will receive are classified as inert, that is, they do not contain municipal solid waste, putrescible waste, or hazardous waste, and other types of waste that may contribute contaminants of concern to underlying groundwater. The monofill will be comprised of ten major cells to be constructed over time, beginning with Cell A (or, possibly B), in the southwest corner of the monofill. The working face receiving the inert materials will comprise, at any one time, an area measuring

39371 San Thomas Court • Murrieta, CA 92562 • Cell: (951) 805-1100 • E-mail: smaddox@ca.rr.com

approximately 120-feet by 50-feet. Therefore, the surface area of the monofill most vulnerable to infiltration by precipitation at any one time will be kept to a minimum.

The proposed monofill meets Alaska State requirements for inert landfills. No liner is required and the base of the inert materials will be 10-feet above the water table.

The glacially-derived sediments beneath the site contain an unconfined aquifer of significant thickness. The calculated volume of groundwater flowing beneath the footprint of the proposed monofill is in excess of 6-million gallons per day. The base of the inert materials within the proposed monofill will be a minimum of 10-feet above the seasonal high water table, and will not be immersed in water. Kikuchi (2013) concluded that the groundwater system is in a state of dynamic equilibrium, characterized by water-level fluctuation about a constant average state, with no long-term trends in aquifer-system storage. Thus, no long-term fluctuation in groundwater levels beneath the site are likely to occur, and the initial minimum separation of the inert materials from the water table will be maintained.

Leaching analysis was conducted on three residual samples of typical shredded monofill materials (such as will be deposited at the proposed Palmer monofill) by SGS Laboratories, Anchorage, Alaska (**Appendix A**). The material came from stockpiled materials at Central Recycling Service's (CRS) facility in Anchorage, Alaska. No contaminants considered to be hazardous by the Alaska Department of Environmental Conservation (ADEC) were detected in the leachate. It appears that the constituents present in the inert materials will not present a threat to the water table at the site.

Studies of leachates produced by inert landfills by the U.S. Environmental Protection Agency (USEPA) and other agencies concluded that an unlined inert landfill may be properly permitted if the site is properly evaluated in advance, only inert non-deleterious materials are landfilled, and the site is properly managed during its lifetime and following closure. The procedures specified in the Operations Plan for the monofill conform to these recommendations.

The USEPA determined that there are seven constituents that are problematic in leachates derived from inert landfills. They are: 1,2-DCA, Methylene chloride, Cadmium, Iron, Lead, Manganese, and Total Dissolved Solids (TDS). Only one of these problematic constituents was detected in the leachate from the inert materials tested by SGS Laboratories, and that was manganese, considered to be non-hazardous.

The annual precipitation in the area around Palmer, Alaska is approximately 15.49-inches. A portion of this rainfall will infiltrate the surface of the monofill, and a larger portion will run off the surface. Compaction of the inert materials during filling operations will reduce the void ratio and the ability of water to move through the materials will be significantly reduced. This will reduce the rate of infiltration and increase the rate of runoff. Numerous studies have determined that infiltration is increased in the summer and reduced in the winter. The long period of reduced temperatures will reduce infiltration of precipitation.

Groundwater modeling was conducted in order to understand the movement and concentrations of potential contaminants in the highly permeable aquifer beneath the site. Three constituents that are commonly the result of human activities, and each of which is a carcinogen, were selected for modeling. They are 1,2-DCA, PCE, and benzene. These compounds are not allowed as constituents in the inert materials to be deposited at the monofill, however the unintended/accidental release of one or more of these chemicals within the monofill could have a detrimental impact on the aquifer. This would be a "worst case" condition, so they were chosen as the subject of this model.

The results indicate that after travelling approximately one-mile, all of these contaminants experienced a very significant reduction in concentration, ranging from 70% to 96%. The demonstrated decline in concentration of all three of these chemicals over time and distance is an indication that they are breaking down chemically and will essentially cease to be present in detectable concentrations after a relatively short transport distance beyond the monofill boundaries. There is no indication that any of these compounds, were they to be present, would reach the groundwater beneath the site due to the very low likelihood of any liquids passing through the thickness of the monofill.

Our review of the proposed monofill, including the inert materials it will receive, it's construction, operations, closure plans, geologic/hydrogeologic setting, apparent unlikelihood of significant infiltration, and groundwater modeling results indicate that the site will not pose a threat to the underlying aquifer.

2.0 INTRODUCTION

Maddox & Associates, Inc. (M&A) was asked to review the plans and procedures for the construction of an inert monofill near Palmer, Alaska. The main goal was to evaluate the potential for possible contamination of the underlying aquifer by leachate that might be released from the inert refuse.

M&A has experience evaluating contamination potential and associated landfill problems at over 50 sanitary landfills. This work has been conducted in all of the regions of the United States and in Canada.

M&A was provided with copies of the "Inert Waste Monofill Solid Waste Permit Application", with all of its attachments, one of which was the "Operations Plan" for the monofill. In addition, M&A was provided with numerous other documents and communications pertaining to the proposed monofill.

Additionally, M&A obtained data pertinent to the geology and hydrogeology in the site area for review and study. Personal communications were conducted with Agencies, laboratories, and other pertinent persons and entities.

The following document is a report on our findings.

2.1 SITE DESCRIPTION

The proposed monofill will be located on 120 acres located on tax lot C10, in Township 17 North, Range 2 East, Section 18 in the Seward Meridian and tax lot B6 located within Township 17 North, Range 2 East, Section 19 in the Seward Meridian, within Palmer, Alaska (**Figure 2.1**).

Lot C10 is in the southwest corner of Section 18 and Lot B6 is north of the Glenn Highway in the northwest corner of Section 19.

The site has historically been used as a gravel pit. The site contours vary greatly as different sections of the lot have been mined for gravel, with elevations ranging from 80 feet above mean sea level (amsl) to 150-feet amsl. The surrounding slopes are at the natural angle of repose for the native soils, and in some cases as steep as 2:1.

The monofill will occupy 35.5 acres over lots C10 and B6 and maintain a 100-foot buffer from the existing industrial ponds located on the property (**Figure 2.2**).

The natural soils on-site vary from well-graded sandy gravel, to areas of clay and silt that were not suitable for mining. The three industrial ponds within the property are reported to be as deep as 90 feet. The ponds are manmade and caused by past industrial gravel dredging. These water bodies do not have inflowing or out-flowing surface water and are fed primarily by groundwater and some onsite surface flow.

Permafrost has not been encountered at any time on the site during historical use and the area of Palmer is in a sporadic permafrost zone. The likelihood of permafrost at the site is low.

The Matanuska River lies approximately 0.7-miles to the southeast. This river ultimately discharges into the Knik Arm, located approximately 4.5-miles to the southwest.

Annual precipitation is reported to be approximately 15.49-inches.

2.2 SITE CONCEPTUAL MODEL (SCM)

The purpose of the Site Conceptual Model (SCM) that follows is to provide a brief, overall understanding of the proposed monofill and its relation to the underlying aquifer. It is placed at the beginning of this document to provide the reviewer with the key elements needed to properly evaluate the proposed project as the review progresses.

The proposed monofill will be comprised of 35.5-acres, located within the southwest corner of a 120 acre plot of land south of Palmer, Alaska. The materials it will receive are classified as inert, that is, they does not contain types of refuse such as general municipal solid waste, putrescible waste, or hazardous waste, and other types of waste that are known to contribute significant contaminants of concern to underlying groundwater.

The monofill will be comprised of ten major cells to be constructed over time, beginning with Cell A (or, possibly B), in the southwest corner of the monofill. The working face receiving the inert materials will comprise, at any one time, an area approximately measuring approximately 120-feet by 50-feet. Therefore, the surface area of the monofill most vulnerable to infiltration by precipitation at any one time will be kept to a minimum.

The site is located in an area underlain by glacial outwash materials, typically sands and gravels, with some minor clays/silts. These granular glacial sediments contain an unconfined aquifer of significant thickness which underlies the site. Calculations of the volume of groundwater flowing beneath the footprint of the proposed monofill are in excess of 6-million gallons per day--flows of this magnitude are not uncommon in these types of materials. The base of the inert materials within the proposed monofill will be a minimum of 10-feet above the seasonal high water table, and will not be immersed in water.

Leaching analysis was conducted on three residual samples of typical shredded monofill materials (such as will be deposited at the proposed Palmer monofill) by SGS Laboratories, Anchorage, Alaska (**Appendix A**). The material came from stockpiled materials at Central Recycling Service's (CRS) facility in Anchorage, Alaska. The results indicate that no contaminants considered to be hazardous by the Alaska Department of Environmental Conservation (ADEC) were detected in the leachate. Only sulfate, manganese, sodium, and zinc were detected at or above laboratory detection limits. Of these, only manganese and sulfate were detected at concentrations above the secondary Maximum Contamination Limit (MCL). Secondary MCLs are non-enforceable guidelines regulating contaminants that may cause cosmetic effects (such as skin or tooth discoloration) or aesthetic effects such as taste, odor, or color). It appears that the constituents present in the inert materials will not present a threat to the water table at the site.

The leaching method employed on the shredded monofill materials was the Synthetic Precipitation Leaching Procedure (SPLP); this method is recognized and accepted by the Unite States Environmental Protection Agency (USEPA).

Based upon the annual precipitation amount and patterns, and the mechanics of infiltration, it is not likely that a significant volume of liquids will pass through the monofill bottom into the water table.

Groundwater modeling, by use of the FlowPath II Ver. 1.3.2.1 software, indicates that, in the unlikely circumstance that any contaminants that are a risk to human health may enter the groundwater beneath the site, they would not travel significant distances before their concentrations would be reduced to relatively low levels. The modeling results will be used to determine the proper location of guard wells to intercept any such contaminants, allowing for the early detection of any groundwater contamination by fluids that may originate in the monofill.

The SCM indicates that the construction and operation of the proposed monofill is not likely to have a detrimental impact on the groundwater beneath or down-gradient of the site.

3.0 MONOFILL DESCRIPTION

The proposed monofill will comprise approximately 35.5 acres, and will reach a maximum height of 150-feet above mean sea level, about the same height as the highest level currently on the property (**Figure 3.1**).

The inert debris brought to the site will be primarily building demolition debris. Some of the material will come directly from demolished buildings in the Matanuska-Susitna Borough. Most of the waste material will be processed and shredded residual recycling waste material. Shredded residual material is a variety of non-hazardous, inert material which is shredded to a size of approximately 12-inches and smaller. This material is the by-product of a recycling facility in Anchorage, Alaska called Central Recycling Services. Central Recycling Services (CRS) specializes in recycling inert construction and demolition waste. CRS will also operate a recycling facility at Palmer to process construction and demolition debris. The material brought to CRS will be both manually and mechanically sorted, screened, and processed through to ensure that the material is free of hazardous material, putrescible material and/or liquids. The shredded inert material will be placed on a trailer and hauled to the monofill in Palmer.

The following materials are not allowed into the monofill:

- PCBs
- Household waste
- Putrescible waste
- Liquids
- Compressed gas cylinders
- Batteries
- Appliances with CFC/HCFC
- Chemical Waste
- Animal carcasses
- Petroleum contaminated materials

Control of Organic Material:

- No organic soils will be allowed to be in contact with any inert debris or tire bales used in the landfill;
- No organic materials other than dry wood construction debris will be allowed in the landfill;
- Clean tire bales (no organic debris attached) will be used for construction of berms or subgrade structural fill.

CONDITIONAL USE PERMIT SITE PLAN - PALMER MONOFILL
DATE: 11/29/13
SCALE: AS SHOWN
REVISED:

Following are the types of materials allowed into the monofill:

The monofill could accept anything allowed by the ADEC permit. The monofill is regulated by the ADEC to protect the public health, safety, convenience, and welfare.

Waste Placement:

The inert material will be placed to fill the natural and manmade dry voids of the property and take advantage of all the onsite features such as existing material berms and valleys.

The elevation of the bottom layer of the waste disposal cells will be established using historical groundwater information. This historical groundwater information was measured over four seasons to determine the seasonal high groundwater elevation. The bottom cell will be located a minimum 10 feet above the established seasonal high-water levels.

A total of 10 cells main will be constructed over the life of the monofill; the cells will be identified as A through I. The first cell to be constructed will be Cell A or B, with the rest of the cells being constructed in the order which best facilitates progress of the filling operations.

After each cell lift is filled completely (See **Figure 3.2** for typical cell sections), a bulldozer will spread 6"-12" of excess soil, strippings, and non-organic overburden on top of the cell's inert debris, creating a fire barrier.

As the top sections of the monofill are completed to final height, 24-inches of native or imported soil will be spread over the top to serve as a final cap and to allow the re-establishment of vegetation on the site within a reasonable period of time.

Slopes will be established as the monofill is constructed to maintain structural stability of the filled materials and to establish the necessary surface drainage to divert as much surface water as possible off of the monofill surface and thus minimize the amount of potential infiltration of water into the inert debris. The slopes will be 2:1 at their steepest when reinforced with tire bales, and 3:1 or less everywhere else. These are slopes of significant grade:

- 2:1 = 50% grade
- 3:1 = 33% grade

Where present, such grades will greatly facilitate the flow of precipitation from the monofill surface, thus significantly reducing the amount of infiltration into the refuse.

Alaska State requirements are met for inert landfill with respect to the following:

- Minimum separation from water table of 10 feet
- No liner required

4.0 PHYSIOGRAPHY

The site is located within and at the easterly end of the Matanuska-Susitna Valley, approximately 3.5 miles to the south-southwest of the City of Palmer, Alaska. The surface relief has been influenced by the most recent glacial advance through the area. It is known as the Naptowne advance of the Matanuska Glacier. The retreat of the glacier left behind a number of geomorphic landforms in the area, two of which appear to merge in the area of the proposed monofill. The two landforms are the Crevasse-fill-ridge complex and the Palmer Terrace. The Crevasse-fill-ridge topography is that of linear to arcuate ridges, while the Palmer Terrace is a low-lying surface of low relief. Both of these landforms are composed of glacial sands and gravels.

The site has traditionally been used as a gravel pit and the surface is irregular, with elevations ranging from approximately 150-feet above mean sea level (amsl), to a low of approximately 80-feet amsl. The nearest bodies of water are three industrial ponds caused by past industrial gravel dredging; the depth of the ponds is as much as 90 feet.

The site is located approximately 0.7-miles to the northwest of the bank of the Matanuska River.

5.0 GEOLOGY

5.1 GEOLOGIC SETTING

Per Kikuchi (2013), the Matanuska-Susitna Valley is in a structural trough bounded by two faults: the Castle Mountain Fault to the north and the border Ranges Fault to the southeast (**Figure 5.1**). **Figure 5.1** depicts the geology of the Matanuska-Susitna Valley. The geologic history of the Matanuska-Susitna Valley includes three major time periods. The Mesozoic Era geology includes the roots of the Talkeetna and Chugach Mountains, comprising intrusive and extrusive igneous rocks adjacent to metamorphic rocks and deep, thick sedimentary layers. The Tertiary period geology includes the Chickaloon and Arkose Ridge Formations abutting the Talkeetna Mountains, as well as the oil-bearing Kenai Group in the Cook Inlet Basin. Finally, the basement rock generated during these two periods is overlain by unconsolidated Quaternary sediments of glacial and non-glacial origin. These sediments are highly permeable in places and comprise the most productive aquifers in the Matanuska-Susitna Valley. The subject site is underlain by the highly permeable Quaternary sediments of glacial origin, forming a very productive aquifer.

5.2 GEOLOGIC UNITS IN THE SITE AREA

The description of the geologic units in the area of the site is taken from Munter (April 2010). The surface geology has been influenced by the most recent glacial advance through the area. It is known as the Naptowne advance of the Matanuska Glacier. The retreat of the glacier left behind a number of geomorphic landforms in the area, two of

which appear to merge in the area of the proposed monofill. The two landforms are the Crevasse-fill-ridge complex and the Palmer Terrace. Both of these landforms are composed of glacial sands and gravels. Kikuchi includes these sediments as part of the Holocene Outwash and Alluvium unit (**Figure 5.2**). **Figures 5.3** and **5.4** show, respectively, hydrogeologic section lines and the corresponding hydrogeologic sections showing the water-bearing geologic units.

Palmer Terrace: Munter (April 2010) describes the Palmer Terrace along the Glenn Highway, south of Palmer, as a gently sloping plain of pitted sand and gravel outwash. The terrace is 25 to 50 feet above the current braidplain of the Matanuska River, which is approximately 0.7-miles to the southeast of the site. The terrace contains several natural kettle lakes formed by melting blocks of glacial ice that were buried during sediment accumulation. The largest kettle lake is Meirs Lake, located approximately 1-mile to the northeast of the site, on the easterly side of Glenn Highway, near it's intersection with Outer Springer Loop road.

Crevasse-fill-ridge complex: During the late stages of the glacial ice cover, open crevasses in the ice were filled with accumulations of alluvial sands and gravels that now stand as arcuate ridges adjacent to valleys and lakes where the ice has melted away.

5.3 SITE GEOLOGY

Reference to boring logs for seven groundwater monitoring wells constructed by Environmental Management, Incorporated (EMI) within the site indicate that the geologic materials beneath the site are composed generally of gravel with sand, and minor zones of clay/silt (**Appendix B**). These wells were drilled/constructed between April 22, 2013 and April 24, 2013. The well depths ranged from 15 to 45 feet below ground surface (bgs). Inspection of the boring logs does not present a clear understanding of the actual depth at which groundwater was encountered beneath the site during drilling. However, following well construction and development, the water levels stabilized and the depth to water in the wells located beneath the footprint of the monofill on July 1, 2013 ranged from 26.23 feet to 36.87 feet bgs. The monitoring well locations are shown on **Figure 5.5.**

Reference to Figure 5, Granite Palmer Pit Revised Bedrock Surface Map (TERRASAT, Inc., August 2012) indicates that the approximate depth to bedrock beneath the footprint of the proposed monofill is 120 to 140 feet.

6.0 HYDROGEOLOGY

Kikuchi (2013) states that groundwater-age data collected during previous studies show that water moves quickly through the groundwater system, suggesting that the system responds quickly to changes in climate forcing. Similarly, the groundwater system quickly returns to long-term average conditions following variability due to seasonal or interannual changes in precipitation. These analyses indicate that the groundwater

system is in a state of dynamic equilibrium, characterized by water-level fluctuation about a constant average state, with no long-term trends in aquifer-system storage. Thus, no long-term fluctuation in groundwater levels beneath the site are likely to occur.

The water-table map for the Matanuska-Susitna Valley contained in the 2013 report Kikuchi (**Figure 6.1**) indicates flow through the groundwater system is driven primarily by recharge in the Little Susitna River Valley, located to the north of the Palmer area, following generally north to south paths in the area surrounding Wasilla and transitioning to northeast to southwest flow paths in the area near Big Lake (Kikuchi, 2013). Groundwater flow in the site area is primarily to the south and west, from the foothills of the Talkeetna Mountains to discharge along the Matanuska River and its contributing sloughs and tributaries.

Numerous closed-basin lakes (lakes with no surface water outlet) occur in the area of the site. Examples are lakes such as Meirs Lake in the pitted outwash of the Palmer Terrace and the long, narrow arcuate lakes between the crevasse-fill ridges in the Kepler-Bradley lakes area. These are groundwater flow-through type lakes, receiving groundwater inflow on the up-gradient side of the lake, and contributing lake water to the groundwater system on the down-gradient side. Kikuchi (2013) states that most of the lakes in the Matanuska-Susitna Valley are hydraulically connected to the groundwater system.

6.1 SITE HYDROGEOLOGY

Munter (April 2010) states that there are two aquifers in the area of the site:

Alluvial or Glacial Outwash Aquifer: This aquifer is the principal aquifer in the site area and is comprised predominantly of alluvial and glacial outwash sand and gravel. This aquifer occurs under water-table conditions in the site area, with limited areas where the groundwater is confined. The aquifer thickness ranges from approximately 50 to 250 feet thick in most areas, although it may be thinner or thicker locally. Reference to Figure 5, Granite Palmer Pit Revised Bedrock Surface Map (TERRASAT, Inc., August 2012) indicates that the thickness of the aquifer material is approximately 120 to 140 feet thick beneath the proposed monofill. The aquifer material is underlain by bedrock. High-yield irrigation or public-supply wells are constructed in some locations. Freethy and Scully (1980) state that wells located in alluvium adjacent to present rivers have yields that may exceed 4,000 gallons per minute (over 5,000,000 gallons per day).

Bedrock Aquifer: This aquifer, underlying the Alluvial or Glacial Outwash Aquifer, is comprised of sedimentary, metamorphic, or igneous rocks (bedrock) that occur at depth throughout the area. Well yields are typically low.

As discussed in Section 5.3, based upon review of boring logs for seven groundwater monitoring wells installed in April 2013, the geologic materials beneath the site are composed generally of gravel with sand, and minor zones of clay/silt. The well depths ranged from 15 to 45 feet below ground surface (bgs). Inspection of the boring logs does not present a clear understanding of the actual depth at which groundwater was

encountered beneath the site during drilling. However, following well construction and development, the water levels stabilized and the depth to water in the wells located beneath the footprint of the monofill on July 1, 2013 ranged from 26.23 feet to 36.87 feet bgs. The monitoring well locations are shown on **Figure 5.5.**

Following is a discussion of the groundwater in the Palmer area contained in Freethy and Scully (1980):

"The deposits beneath the present valley floors of the Matanuska and Knik rivers are generally unconfined; that is, ground water exists under atmospheric pressure. Till sheets and less permeable lenses cause some local confinement, but nearly the entire area is readily recharged by infiltrating precipitation and seepage from the Matanuska and Knik rivers. Numerous bedrock outcrops indicate that the thickness of alluvium is not great. Groundwater is being withdrawn from relatively continuous sand-and-gravel beds in outwash deposits and Holocene stream alluvium. Well yields range from 5 to 75 gallons per minute in areas away from large recharge sources and where localized confinement occurs. Yields may exceed 4,000 gallons per minute in alluvium adjacent to present rivers."

6.2 STUDY BY J.A. MUNTER: POTENTIAL HYDROLOGIC EFFECTS OF GRAVEL EXTRACTION SOUTH OF PALMER, ALASKA

James A. Munter (April 2010) conducted an evaluation of the effects of gravel extraction in two pits proposed for the site area. Granite Construction Company (Granite) has a sand and gravel mining operation going on just across Glenn Highway, approximately 0.5-miles to the southeast, between the site and the Matanuska River.

Munter used a model (Theiss, 1935) to estimate water level declines resulting from the sand and gravel mining operations to be conducted near the site by Granite. The depths of Granite's operations are reported to be 50 to 150-feet below the ground surface, extending far below the water table.

Granite's gravel mining operations will extend the pit into the braidplain of the Matanuska River. The result will be a lake with a surface elevation of approximately 49-feet amsl, matching that of the water table in that area. The permeable alluvium at the site makes it likely that a good hydraulic connection will be present between the lake and the water table.

The model indicates that after one year, water table declines of several feet attributable to the gravel pit could extend 1.5 miles or more in a generally northward direction from the newly-formed lake. The site of the proposed monofill lies well within this 1.5-mile distance of water-table lowering.

Kikuchi (2013) discusses Munter's study on page 4 of his paper. He reports Munter's conclusions of a lowering of the water table in the site area with no disagreement.

The planned elevation of the bottom of the inert refuse in the monofill is a minimum of 10-feet below the normal seasonal high. If the water table in the area of the monofill is lowered by "several feet", it will increase the distance between the base of the monofill material and the water table.

It is our opinion that more data are needed to determine if Munter's conclusions are valid.

6.3 WATER QUALITY IN THE PONDS LOCATED WITHIN THE SITE

On December 5, 2012 SLR International Corporation (SLR) obtained one surface water sample from each of the three ponds occupying the three abandoned gravel pits on the north side of the Granite Construction Palmer Facility. The following scope of work was completed:

- A hand auger was used to drill a hole through the ice at two of the three locations. Open water was accessible at one location.
- Water quality parameters pH, conductivity dissolved oxygen, oxidation-reduction potential, and temperature were monitored using a YSDI 556 multi-meter prior to sampling and recorded on sampling forms.
- Three surface water samples and one duplicate were collected using disposable bailers and transferred to laboratory sampling containers.
- Samples were hand delivered to SGS North America, Inc. (SGS) in Anchorage, Alaska for analyses.

All work was completed by Alaska Department of Environmental Conservation (ADEC) qualified personnel under 18 AAC 75.990(100).

Analyses:

Three surface water samples (GCP-1, GCP-2, and GCP-3) were tested for RCRA Metals by EPA Method 6000/7000 series, benzene, toluene, ethylbenzene, and xylenes (BTEX) by EPA Method 8021, nitrate/nitrite by SM 4500-NO_3 , fecal Coliform bacteria SM 9222, and total dissolved solids by SW2540C.

Results:

BTEX: None detected (ND) at or above laboratory detection limits

Fecal Coliform bacteria: None detected at or above laboratory detection limits
RCRA metals: Only barium was detected above laboratory detection limits, with concentrations ranging from 25.8 µg/L to 39.3 µg/L--these are below the Alaska Drinking Water Standard of 2,000 µg/L.

Total nitrate/nitrite as nitrogen: Detected in all three samples at concentrations ranging from 1870 µg/L to 2200 µg/L--these are below the Alaska Drinking Water Standard of 10,000 µg/L (10 mg/L).

Phosphorous: Detected in all three samples at concentrations ranging from 0.06 to 0.1 mg/L. There is no Alaska Drinking Water Standard for phosphorous.

TDS: TDS in the three samples ranged from 325 mg/L to 359 mg/L, and did not exceed Alaska Water Quality Standards.

Comparison to City of Palmer Water System:
An analysis of water from the Palmer water system was obtained through the State of Alaska Drinking Water Watch web-page. The comparisons are as follows:

Granite Ponds	Palmer water system
Barium 25.3 µg/L to 39.3 µg/L	20.8 µg/L
Nitrate/nitrite 1870 to 2200 µg/L	0.987 mg/L

The City of Palmer analyses were performed on 7/19/13. RCRA Metals analyses and nitrate/nitrite and were the only analytes for which the City of Palmer tested. Only barium and nitrate/nitrite were detected above the laboratory detection limits.

Based on the measured parameters, the quality of the water in the three ponds on the subject site is not as good as the water in the Palmer water system, but it does not exceed Alaska Drinking Water Standards.

Relation of Water in the Three On-Site Ponds to Groundwater:

Both Kikuchi (2013) and Munter (April 2010) state that the lakes (and by association, the ponds) are groundwater flow-through types receiving groundwater inflow on the up-gradient side of the lake, and contributing lake water to the groundwater system on the down-gradient side. As noted above, Kikuchi (2013) states that most of the lakes (and by association, the ponds) in the Matanuska-Susitna Valley are hydraulically connected to the groundwater system. Site data indicate that the ponds on the site are man-made industrial ponds caused by past industrial dredging. These bodies do not have inflowing or out-flowing water and are fed by onsite surface flow and groundwater. Based upon this evaluation, it appears that the analyses of the three ponds on the subject site also apply to the groundwater within the site.

7.0 RELATION OF PROPOSED MONOFILL TO AREA HYDROGEOLOGY

7.1 RESULTS OF LEACHING OF TYPICAL MONOFILL MATERIAL

EMI submitted three samples of shredded inert waste materials to SGS for analyses by the Synthetic Precipitation Leaching Procedure (SPLP). This method uses a solution of

acetic acid in water to leach the components of the subject materials. The shredded monofill materials were composed generally of:

- Metals
- plastics
- Foam
- Insulation
- Drywall
- Wood (the majority of the material)

This material was collected from the CRS recycle facility and is representative of the inert shredded materials that will be placed in the Palmer monofill.

The leachate produced by the SPLP procedure was analyzed by the following methods:

- SW 6020 SPLP: metals by ICP/MS SPLP SW1312
- SW9045C: pH, Soil (S)
- SW8270D SPLP: Semi-Volatile SPLP Liq/Liq
- SW1312/8260B: SPLP Volatile Organic Compounds 8260
- SW 300.0: Sulfate

The results are contained in Table 7.1:

TABLE 7.1
RESULTS OF ANALYSES OF SHREDDED MONOFILL MATERIALS

SAMPLE	PARAMETER	RESULT	ALASKA DRINKING WATER STANDARDS
Residual A	pH, corrosivity	6.10	6.5--8.5
	Manganese	*0.384 mg/L	0.05 mg/L
	Sodium	65.4 mg/L	None
	Zinc	2.22 mg/L	5.0 mg/L
	Sulfate	*591 mg/L	250 mg/L
Residual B	pH, corrosivity	6.04	6.5--8.5
	Manganese	*0.347 mg/L	0.05 mg/L
	Sodium	53.0 mg/L	None
	Sulfate	*520 mg/L	250 mg/L
Residual C	pH, corrosivity	6.61	6.5--8.5
	Manganese	*0.373	0.05 mg/L
	Sodium	66.5	None
	Sulfate	673 mg/L	250 mg/L

* Exceeds Alaska State Drinking Water Standards

It should be noted that only three analytes were detected above laboratory detection levels in the leachate derived from the SPLP method. Of these, only manganese and sulfate exceeded the Alaska State Drinking Water Standards. The standards for manganese and sulfate are Secondary Standards. Secondary Standards are non-enforceable guidelines regulating contaminants that may cause cosmetic effects (such as skin or tooth discoloration) or aesthetic effects (such as taste, odor, or color) in drinking water. Sulfate detected by SGS is not considered a problematic constituent by the USEPA. Sodium, which was detected in the leachate from all three samples, is considered to be an essential nutrient and is not regulated.

7.1.1 OTHER STUDIES INVESTIGATING THE POTENTIAL IMPACT OF LEACHATES DERIVED FROM INERT LANDFILLS ON GROUNDWATER

The results of three studies will be discussed in this section.

A. *"Construction and Demolition Waste Landfills"*, Prepared for U.S. Environmental Protection Agency, Office of Solid Waste by ICF Incorporated, Contract No. 68-W3-0008, February 1995; May 18 1995 Draft Report:

This study addressed construction and demolition (C&D) leachate quality. Sampling data were collected for 305 parameters from a total of 21 C&D landfills. Of the 305 parameters, 93 were detected at least once. Of the 93 parameters detected, 24 had at least one measured value above the regulatory or health-based benchmark. Based on (1) the number of landfills at which the benchmark was exceeded and (2) a comparison between the median detected concentration and the benchmark, seven constituents emerged as being potentially problematic. They are listed in the table below:

TABLE 7.2
C&D LANDFILLS
SEVEN CONSTITUENTS THAT ARE PROBLEMATIC IN LEACHATE

CONSTITUENT	NO. OF LANDFILLS SAMPLED	NO. OF LANDFILLS DETECTED	NO. OF LANDFILLS > BENCHMARK	RATIO OF MEDIAN TO BENCHMARK
1,2-Dichloroethane	9	3	3	4
Methylene chloride	9	4	3	3
Cadmium	19	14	12	2
Iron	20	20	19	37
Lead	18	15	13	4
Manganese	14	14	13	59
Total Dissolved Solids	18	17	15	4

It should be noted that for three of the seven parameters listed in Table 7.2, (iron, manganese, and TDS) the benchmarks are secondary MCLs, which are set to protect water supplies for aesthetic reasons. The remaining four parameters did not greatly exceed MCLs, so their concentration in groundwater are likely to fall below health-based benchmarks.

Only one of the seven problematic constituents was detected in the leachate derived from the shredded monofill materials representative of those to be filled at the Palmer site, and that constituent (manganese) is only problematic due to aesthetic concerns. It is apparent that if leachates derived from the typical monofill materials enter the groundwater beneath the proposed monofill, the groundwater will not be negatively impacted.

B. *"A Comparison of Selected Parameters from Ohio Construction and Demolition Debris Leachate with Ohio Municipal Solid Waste Leachate"*, Ohio EPA, Draft: June 12, 2009

The Conclusions section of this report stated:

Ohio EPA is often asked "Which leachate is cleaner?" The appropriate response is, "They are both of concern." Both types of leachate have numerous parameters that exceed U.S. EPA primary drinking water standards, which for C&D leachate is contrary to the industry literature (National Demolition Association, 1995). Both types of leachate would violate Ohio discharge limits to groundwater and surface water if released to the environment. Both types of leachate pose threats to public health and the environment if released to groundwater or surface water from organic compounds, metals, and inorganic compounds. The degree of risk associated with the threat from a release of either type of leachate will be dependent upon how the material in the landfill was disposed, the location of the landfill, site conditions, leachate management, closure, post-closure care, and circumstances surrounding the site, which often change over time.

It is apparent that this study revealed that, under certain conditions and circumstances, inert landfills can produce leachates that will negatively impact groundwater in the area of the landfill. It is also apparent that proper restrictions on the types of inert wastes disposed in the monofill and proper management of the site will greatly lessen the likelihood of groundwater impaction. The management of inert wastes prior to landfilling, as described in Section 3.0 of this document, will greatly lessen the possibility of groundwater contamination.

C. Memorandum from Carl Anderson, P.G., Administrator, Solid and Hazardous Waste Division, Wyoming Department of Environmental Quality, August 29, 2011, *"Screening Criteria for Operation of Unlined Construction/Demolition Disposal Facilities."*

The conclusions of this memorandum was that C/D wastes and C/D leachates are not benign, but C/D leachate has less capacity to cause environmental impacts. So, a relatively limited site evaluation may provide adequate data to determine site suitability for use as an unlined landfill.

CONCLUSIONS TO BE DRAWN FROM OTHER STUDIES PERTAINING TO THE PROPOSED MONOFILL:

A proposed unlined inert landfill may pose no harm to the environment or public health if the site is properly evaluated in advance, only non-deleterious materials are landfilled, and the site is properly managed during its lifetime and following closure. These conditions are met in the proposed monofill to be constructed at the Palmer site.

Additionally, the observed effects of landfills on groundwater, in general, in the Anchorage, Alaska area are described in *"Water Quality Assessment of the Cook Inlet Basin, Alaska–Summary of Data through 1997"*, USGS Water-Resources Investigations Report 99-4116, National Water-Quality Assessment Program

On page 49 the following statement is made:

"Leachates from landfills contain high concentrations of dissolved solids. Madison and others (1988) report that leachates from two Anchorage landfills contain large concentrations of iron, manganese, and organic carbon. The leachates have concentrations of dissolved solids ranging from 2 to 20 times greater than adjacent, unaffected groundwater. Ground-water contamination by landfills in the study unit **appears to be limited to areas immediately adjacent to the landfills**. The Merrill Field landfill in Anchorage was used from the 1940's through 1987. Minor amounts of contaminants have reached distances about 2,200 feet from the site, but concentrations are generally less than MCLs except for those within the landfill itself.(Brunett, 1990)."

This may indicate that, in areas where there is a significant flow of groundwater in the subsurface, contaminant concentrations diminish rapidly outside the footprint of the landfill.

7.2 POTENTIAL FOR INFILTRATION OF PRECIPITATION INTO THE MONOFILL

The annual precipitation in the area around Palmer, Alaska is approximately 15.49-inches per year. A portion of this rainfall will infiltrate the surface of the monofill, and a larger portion will run off the surface.

Infiltration is the process by which water enters the soil. It separates water into two major hydrologic components--surface runoff and subsurface recharge. The infiltration rate usually shows a sharp decline with time from the start of the application of water. The constant rate approached after a sufficiently large time is referred to as the steady-infiltration rate. The process is described by the equations of Kostiakov (1932) and Horton (1040), which show a decreasing infiltration rate as a function of time.

A dry soil will have a higher infiltration rate than a soil with a high water content; this is due to the decreasing infiltration rate the closer the soil gets to its saturation point. A

fully-saturated soil becomes almost an impermeable layer (**Lund Institute of Technology, 2011**)

Typically, in summer, infiltration is greater than in winter. More overland flow (runoff) can be expected in winter than in summer (**Diamond and Thomas, 2013**). This is true in freely drained soils that have not been compacted. Compacted materials will produce more copious overland flow. A low soil temperature will slow the infiltration or fully prevent it if the soil is frozen (**Lund Institute of Technology, 2011**). Low soil temperatures are present for a significant portion of each year at the site, thus the susceptibility to infiltration of precipitation is reduced during the cold weather portion of the year.

The active working area of the site, where daily dumping, compaction, and covering is conducted, will cover, on average, approximately 120-feet by 50-feet. This will vary from day to day.

When water is applied to the active filling area of the monofill and the refuse is compacted, the void spaces in the refuse will be filled, the permeability of the material will be greatly lessened, and the amount of runoff will be increased, thus infiltration will be reduced.

When the inert materials are compacted, as they will be during the filling operations, the void ratio is reduced and the ability of the water to move through the materials is significantly reduced. However, the area of the active filling will allow more infiltration than the adjacent areas with soil cover.

Sloping and proper grading procedures will direct free water off the surface and the amount of runoff will be further increased. The result is that much more water will be runoff over the site as a whole than that which infiltrates.

Page 11 of the Operations Plan for the monofill submitted as a part of the Inert Waste Monofill Solid Waste permit Application, dated January 2013, states that, "A SWPPP plan will be in effect, in conjunction with grading plans to direct surface water off the monofill and onto the surrounding land surface and into the drainage basin composed of industrial water." The SWPP will be in effect during construction in areas that allow water to flow off-site. Page 9 of the Operations Plan states that, "Side slopes will be 2:1 at their steepest when reinforced with tire bales and 3:1 or less everywhere else." These are slopes of significant grade:

- 2:1 = 50% grade
- 3:1 = 33% grade

As stated above, where present, such grades will greatly facilitate the flow of water from the monofill surface, thus significantly reducing the amount of infiltration into the refuse.

It is important to note that the area of active filling, at any one time, will be small compared to the entirety of the surface area of the particular cell being worked. As stated above, the active working area of the site, where daily dumping, compaction, and covering is conducted, will cover, on average, approximately 120-feet by 50-feet. This will vary from day to day. Thus only small areas of inert refuse will be exposed to the elements.

7.2.1 DESCRIPTION AND SIGNIFICANCE OF RAINFALL OCCURRENCE

As stated above, the average rainfall in Palmer, Alaska is 15.49-inches. It is of interest to note that the average annual precipitation in the City of Los Angeles, California is very similar to that of Palmer--it is approximately 15.0-inches. Both locations are considered to be semi-arid, without significant annual precipitation.

Discussions with local residents indicate that most of the 15.49-inches of rainfall normally occurs during two seasons:

- Spring
- Fall

Normally, only minor rainfall occurs during the summer.

It is, therefore, apparent that the annual rainfall of 15.49 inches per year does not get spread out at an average rate over the entire year-long period.

Rainfall records for the Palmer area were reviewed for the period 10/1/12 through 11/30/23. Rainfall in the Palmer area occurs in episodes of a couple of days to a week, with the average of the longer periods being approximately 4 days of consecutive rain. Most rainy episodes last for one to two days. Following such a period of rainfall, it is common for no additional rain to fall for a week or more. Over the last 12 months, there have been 11 periods of no rain lasting for two to three weeks at a time.

Based on the mechanics of infiltration, the short periods of intense rain will result in more surface runoff, and less infiltration, than if the rainfall were spread out evenly over a 12-month period. Consequently, with short, intense periods of rainfall, the upper zone of the soil cover will become overloaded with moisture as the pores fill and become clogged with water. This will result in reduced permeability, increased runoff, and reduced infiltration.

In between periods of rainfall, the upper horizons of the refuse will tend to dry out due to evapotranspiration and the cycle will begin again with the next period of rain. This cyclic process will result in the minimization of infiltration and maximization of evapotranspiration.

It is difficult to estimate the actual volume of water per unit of surface area that may penetrate into the monofill because of the relatively small daily working area, but with

this type of cyclic process, it is likely that none of the precipitation will make its way through the considerable thickness of the proposed monofill. It follows, then, that it is unlikely that any of the monofill constituents will leach into the water table.

7.3 MOVEMENT OF GROUNDWATER

Munter (April 2013) considers the transmissivity of the unconfined aquifer in the area of the site to be approximately 100,000 ft.^{2}/day. In an unconfined aquifer, the transmissivity is defined by

T=Kb,

where b is the saturated thickness above the underlying aquitard that bounds the aquifer. K is the hydraulic conductivity of the aquifer materials. General consensus by authors who have studied this area is that the aquifer ranges up to about 200+ feet in thickness, so if this maximum thickness is assumed, and that is the value assigned to b, the value of K is equal to 500 feet per day. Data indicate that the saturated aquifer thickness beneath the proposed monofill site is approximately 120 feet. Using this value, K= 833 feet per day beneath the site. Glacial outwash material typically has a very high yield, and is the second-most important category of aquifer.

The direction of groundwater flow and its gradient were calculated using the groundwater contour map constructed by TERRASAT titled "Monofill Water Table 7-1-13 Contour Map", dated July 31, 2013 (**Appendix C**), and prepared for Environmental Management, Inc. The results show a groundwater flow direction of S 34W, with a gradient of 0.008.

The volume of groundwater flow beneath the site was calculated by use of Darcy's Law:

Q=KIA

where

Q = flow in gallons per day
K=Hydraulic conductivity in feet per day
I=Gradient
A=Area water flows through in square feet

Taking the width of the proposed monofill perpendicular to the direction of groundwater flow, a saturated aquifer thickness of 120 feet, a gradient of 0.008, and K=833 feet per day, the volume of groundwater flowing beneath the site is:

6.7 million gallons per day

This is fits well into the statement by Freethy and Scully (1980) that wells located in alluvium adjacent to present rivers have yields that may exceed 4,000 gallons per minute,

which is approximately 5,760,000 gallons per day. The proposed monofill is located only 0.7 miles from the Matanuska River.

8.0 GROUNDWATER MODELING

The following sections describe the methodology used to conduct groundwater flow and fate and transport modeling at the subject site. Groundwater modeling was conducted in order to understand the movement and concentrations of potential contaminants in the highly permeable aquifer beneath the site. It is not expected that any leachate containing contaminants will reach the aquifer. But if it does happen, it will be possible to understand the fate and transport of these chemicals and their impact on the aquifer.

SELECTION OF CONTAMINANTS TO BE CONSIDERED IN THE MODEL

The laboratory analytical results for the three residual monofill samples showed only the presence of manganese, sodium, zinc, and sulfate (See Table 7.1, above). Of these analytes, only manganese and sulfate were detected above the Alaska State Drinking Water Standards, and as described above, they are not a threat to human health, public safety, or the environment. Manganese, zinc, and sodium are considered to be "essential nutrients", and so are of no environmental concern. Additionally, the fate and transport properties of these metals is such that they tend to be adsorbed onto soil particles in both the unsaturated zone and within the aquifer, and will remain in the immediate area of the monofill.

Since none of the detected analytes are considered to be a threat to human health, they were not included in this model. It should be noted that, for the constituents selected to be modeled, the laboratory analyses of the three residual samples of typical monofill materials showed no detection for these constituents at or above the laboratory detection limits. That means that it is possible that these three constituents could be present at concentrations lower than the detection limits, although the detection limits for these analytes are low. Following are the three constituents chosen for modeling and the reasons for choosing them:

- 1,2-DCA is one of the seven potentially problematic constituents typical of inert landfill leachates (USEPA, 1995), commonly released into the environment by man's activities, it is extremely mobile in groundwater, and it is a carcinogen;
- Benzene is a compound commonly released into the environment by man's activities and it is a carcinogen;
- PCE, a common chemical used to clean metals, is another compound commonly released into the environment by man's activities, and it is a carcinogen.

These compounds are considered to be a threat to human health and are commonly released into the subsurface as the result of human activities. Although these compounds are not allowed as constituents in the inert materials deposited at the monofill, the unintended/accidental release of one or more of these chemicals within the monofill would have a detrimental impact on the aquifer if they were to reach the water table. Release of one or more of them into the groundwater beneath the site is considered to be a "worst case" condition and so they were chosen as the subject of this model.

MODEL DESCRIPTION

The groundwater flow model FLOWPATH© was used to simulate groundwater flow and transport in the shallow aquifer beneath the site. FLOWPATH© is a two-dimensional steady-state groundwater flow and transport that can be used for wellhead protection analysis, calculating hydraulic heads, groundwater velocities, and time-related pathlines and capture zones. FLOWPATH© uses a block-centered finite difference grid and solves the resulting set of algebraic equations by means of the modified iterative alternating direction implicit method. The model simulates unconfined, leaky, or confined flow in a heterogeneous and anisotropic aquifer. Pathlines and capture zones are calculated using a weighted Eularian time integration scheme. Input requirements for the model include a grid size and spacing delineation over known well coordinates, domain boundary, aquifer property, material thickness, leakage factor, pumping well locations, particle release locations, and capture time. During model calculation, a modified iterative alternating direction implicit method was used at a convergence criterion of 0.01 percent. The maximum number of iterations was set at 250, which results in a head discrepancy of less than 0.02 percent. FLOWPATH© has been verified with existing numerical codes including PLASM© and MODFLOW for hydraulic head distribution, and with RESSQ© and GWPATH© for pathlines and travel times, by the author, Waterloo Hydrogeologic Services, Ontario, Canada.

OVERVIEW OF MODELING PRODCEDURES

Groundwater flow modeling was accomplished through the following steps:

1) Conceptualizing a hydrogeologic flow regime,
2) Designing a finite-difference grid system,
3) Assigning model boundary conditions,
4) Assigning a hydraulic conductivity and porosity to aquifer materials,
5) Calibrating the computer model using known measured data and then run the flow model.
6) Input transport parameters such as initial concentrations, dispersivity parameters, retardation factors and decay constants.
7) Run particle tracking (solute transport) and fate and transport components of the model.

HYDROGEOLOGIC FLOW REGION

The model domain consists of a 9000 by 12000 feet area that includes the Site and the surrounding areas. The depth of groundwater beneath the Site occurs approximately 10 feet below ground surface (bgs). Groundwater beneath the Site flows towards the south and southwest. The average hydraulic gradient beneath the study area is approximately 0.008 feet/feet.

For modeling purposes, it was assumed that the shallow groundwater zone beneath the study area consists of a single unconfined layer that is generally comprised of sandy and gravelly materials. The thickness of this layer was assumed to be approximately 120 feet everywhere within the model domain.

Cell A was chosen as the point of possible origin for three chemicals (1,2-DCA, PCE, and benzene) that are serious carcinogens. They have not been detected in the three samples of typical residual materials that will be deposited at the monofill, but were chosen as possible contaminants that might unknowingly be deposited in the monofill. Cell A is the first cell that will be operational and it is located at the extreme southerly tip of the monofill, in an upgradient direction of possible receptors to the south and off the site.

MODEL BOUNDARY CONDITIONS

Water level data from monitoring wells located within the site area indicate that the groundwater flow direction underneath the Site is generally toward the south and southwest. We assumed that the groundwater flow gradient is relatively consistent and does not change significantly with time.

Hydraulic conditions along the boundaries of the grid were defined by specifying a constant head value at each end of the north and south boundaries. Water elevations from the recent period (7-1-13 Terrasat, Inc. Contour Map) were used to simulate the static condition (**Figure 8.1**) Constant head values were placed in a manner that model domain in a configuration to simulate the average hydraulic gradient and contours across the site.

HYDRAULIC CONDUCTIVITY AND OTHER PARAMETERS

The lithologic logs of sediments beneath the Site indicate that saturated sediments beneath the Site are composed of highly permeable sandy and gravelly materials. Aquifer transmissivity of 100,000 ft^2/day was reported, which yields a hydraulic conductivity of the aquifer materials of about 833 feet per day.

A single porosity value of 0.25 was selected based on estimates of ranges of effective porosity for the type of formation that underlies the site, obtained from published data (Driscoll 1986; Freeze and Cherry 1979).

Longitudinal and transverse dispersivity of 10 and 3 feet were assumed, respectively.

MODEL RESULTS

Several model runs were performed to simulate the static groundwater condition, each time the simulated results were compared to the actual field observations of groundwater elevations. After the calibration was completed, fate and transport parameters were input to the model. Three potential chemicals of concern were evaluated: Benzene, PCE and 1, 2-DCA. Data from the lab indicated detection limits of 24.0, 30.0 and 30.0 ug/L for Benzene, PCE and 1, 2-DCA, respectively. This means that, even though none of the three compounds were detected at or above the laboratory detection limits, they may be present below these concentrations. We used a leachate concentration of 10 times these detection limits to be conservative and to show "worst case"; concentrations of these magnitudes would pose s threat to groundwater. The results of the particle tracking and the fate and transport models are presented below.

In order to simulate non-decay concentrations, forward particle tracking was used to calculate travel pathlines. The particles were released down-gradient of the landfill within Cell A and forward tracked. These simulations do not account for the decay of contaminants due to dissolution of contaminants sorbed onto aquifer solids. The simulations are shown on **Figure 8.2** through **Figure 8.4**. It appears that it takes about a year for benzene and 1, 2-DCA to travel about a mile down-gradient of the Cell A, whereas it takes about five years for PCE.

Figure 8.5 through **Figure 8.7** present predicted benzene concentrations for every 6 months for the distance of one mile down-gradient of the Cell A. Similarly, **Figure 8.8** through **Figure 8.10** show the simulated groundwater concentrations for 1, 2-DCA. **Figure 8.11** through **Figure 8.15** show the simulated groundwater concentrations for PCE.

All of these compounds show a significant breakdown and decrease in concentration over reasonably short periods of time relative to the projected life of the monofill. After one year, the greatest distance traveled by any of the compounds is approximately 6,000-feet. It is important to keep in mind that these compounds have not been detected in the typical inert refuse that will be deposited in the monofill. They are only "worst case", and there is no reason to expect that any of these compounds would ever reach the groundwater beneath the site, due to the very low likelihood of any leachate passing through the thickness of the monofill, as described above.

The following two tables will illustrate the modeled distance of analyte travel versus time and analyte concentrations versus time.

MADDOX & ASSOCIATES, INC. 39371 SAN THOMAS CT. MURRIETA, CA 92562 (951) 805-1100	MATANUSKA - SUSITNA VALLEY ALASKA	FIGURE 8.15 PCE CONCENTRATIONS AFTER 5 YEARS	DATE: 11/19/13 SCALE: NONE REVISED:

TABLE 8.1
MAXIMUM CONCENTRATIONS VERSUS TIME

ANALYTE	INITIAL CONC. µg/L	0.5 YR.	1 YR.	2 YR.	3 YR.	4 YR.	5 YR.
BENZENE	240 µg/L	90.4 µg/L	60.6 µg/L	--	--	--	--
PCE	300 µg/L	--	161 µg/L	83 µg/L	83 µg/L	--	12.33 µg/L
1,2-DCA	300 µg/L	120.2 µg/L	90.4 µg/L	--	--	--	--

TABLE 8.2
DISTANCE OF ANALYTE TRAVEL VERSUS TIME

ANALYTE	0.5 YR.	1 YR.	2 YR.	3 YR.	4 YR.	5 YR.
BENZENE	1,650 FT.	4,356 FT.	--	--	--	--
PCE		480 FT.	1,879 FT.	3,343 FT.	--	5,807 FT.
1,2-DCA	1,925 FT.	4,900 FT.	--	--	--	--

Reference to these two tables will indicate that over relatively short periods of time and short distances, the three compounds of concern will be significantly reduced in concentration. This is illustrated by the data contained in the following table:

TABLE 8.3
REDUCTION IN ANALYTE CONCENTRATION OVER TIME/DISTANCE

ANALYTE	DISTANCE	TIME	CONCENTRATION REDUCTION
BENZENE	0.8 MILE	1 YR.	75%
PCE	1.1 MILE	5 YR.	96%
1,2-DCA	0.9 MILE	1 YR.	70%

It should be noted that, after traveling approximately one-mile, all of these contaminants experienced a very significant reduction in concentration, ranging from 70% to 96%. The demonstrated decline in concentration of all three of these chemicals over time and distance is an indication that they are breaking down chemically and will essentially cease to be present in detectable concentrations after a relatively short transport distance beyond the monofill boundaries.

GUARD WELLS

The results of this model will allow for the proper placement of the planned "guard wells" down-gradient of the site. Proper placement of these wells will allow for the earliest possible detection of any contaminants that may pass into the groundwater beneath the monofill. As stated in section 7.2, above, there is little likelihood of any liquids passing through the monofill and entering the groundwater. Also, as stated above, if any of the leached constituents detected in the leachate produced during the laboratory analysis were to reach the water table, they would likely not travel beyond the footprint of the monofill.

9.0 CONCLUSIONS

- The Site Conceptual Model (SCM) describes the monofill as one that, as proposed in structure, operation (during operation and after closure), and location does not pose a threat to the underlying aquifer.

- The hydrogeology in the area is typical of areas underlain by glacial outwash materials (sands and gravels). A study by Kikuchi (2013) indicates that groundwater moves quickly through the system in the area of the site and responds quickly to changes in climate forcing. Similarly, the groundwater system quickly returns to long-term average conditions following variability due to seasonal or interannual changes in precipitation. The groundwater system is in a state of dynamic equilibrium, characterized by water-level fluctuation about a constant average state, with no long-term trends in the aquifer-system storage. Thus, no long-term fluctuation in groundwater levels beneath the monofill are likely to occur.

- Groundwater occurs at depths greater than 10-feet beneath the footprint of the proposed monofill.

- Over 6,000,000-gallons per day of groundwater flow beneath the area of the monofill.

- The aquifer beneath the site is unconfined.

- The three industrial ponds located on the site are in direct hydraulic connection with the water table.

- Leaching tests/analyses of three shredded samples of inert materials typical of the type that will be accepted at the proposed monofill indicated the presence of only non-hazardous materials.

- Studies of leachates produced by inert landfills by the USEPA, the Ohio EPA, and the State of Wyoming indicate that a proposed unlined inert landfill may pose no

health or environmental hazards and be properly permitted if the site is properly evaluated in advance, only non-deleterious materials are landfilled, and the site is properly managed during its lifetime and following closure. The CUP application and the Operations Plan for the proposed monofill indicate that the site meets these criteria.

- The annual precipitation in the area around Palmer, Alaska is approximately 15.49-inches. A portion of this rainfall will infiltrate the surface of the monofill, and a larger portion will run off the surface. As the inert materials are compacted during filling operations the void ratio will be reduced and the ability of water to move through the materials will be significantly reduced. This will reduce the rate of infiltration and increase the rate of runoff. Numerous studies have determined that infiltration is increased in the summer and reduced in the winter. The susceptibility to infiltration of precipitation is reduced during the cold weather portion of the year, a significant period.

- The area of active filling, at any one time, will be small compared to the entirety of the surface area of the particular cell being worked. The active working area of the site, where daily filling, compaction, and covering is conducted, will cover, on average, approximately 120-feet by 50-feet. Thus only relatively small areas of inert materials will be exposed to the elements.

- The annual rainfall of 15.49-inches per year does not occur spread out evenly over the year.

- Rainfall in the Palmer area occurs in episodes of a couple of days to a week, with the average of the longer periods being approximately 4 days of consecutive rain. Most rainy episodes last for one to two days. Following such a period of rainfall, it is common for no additional rain to fall for a week or more. Over the last 12 months, there have been 11 periods of no rain lasting for two to three weeks at a time.

- Based on the mechanics of infiltration, the short periods of intense rain will result in more surface runoff, and less infiltration, than if the rainfall were spread out evenly over a 12-month period. Consequently, with short, intense periods of rainfall, the upper zone of the soil cover will become overloaded with moisture as the pores fill and become clogged with water. This will result in reduced permeability, increased runoff, and reduced infiltration.

- In between periods of rainfall, the upper horizons of the refuse will tend to dry out due to evapotranspiration and the cycle will begin again with the next period of rain. This cyclic process will result in the minimization of infiltration and maximization of evapotranspiration.

- It is difficult to estimate the actual volume of water per unit of surface area that may penetrate into the monofill because of the relatively small daily working

area, but with this type of cyclic process, it is likely that none of the precipitation will make its way through the considerable thickness of the proposed monofill. It follows, then, that it is unlikely that any of the monofill constituents will leach into the water table.

- Groundwater modeling of three hazardous compounds (1,2-DCA, PCE, and benzene) that are typically released into the environment by man's activities indicate that, if they are inadvertently introduced into the aquifer, they will experience significant breakdown in concentration over relatively short periods of time.

- All of the contaminants modeled showed a very significant reduction in concentration, ranging from 70% to 96%. over a distance of approximately one mile.

Our review of the proposed monofill, including the inert materials it will receive, it's construction, operations, closure plans, geologic/hydrogeologic setting, and the unlikelihood of significant infiltration of precipitation indicate that the site will not pose a threat to the underlying aquifer.

LABORATORY ANALYSES OF SHREDDED MONOFILL MATERIALS

SGS

Laboratory Report of Analysis

To: Environmental Mgmt Inc (EMI)
206 E Fireweed Ln #201
Anchorage, AK 995032703
(907)272-9336

Report Number: **1133673**

Client Project: **CMS Monofills**

Dear Larry Helgeson,

Enclosed are the results of the analytical services performed under the referenced project for the received samples and associated QC as applicable. The samples are certified to meet the requirements of the National Environmental Laboratory Accreditation Conference Standards. Copies of this report and supporting data will be retained in our files for a period of five years in the event they are required for future reference. All results are intended to be used in their entirety and SGS is not responsible for use of less than the complete report. Any samples submitted to our laboratory will be retained for a maximum of fourteen (14) days from the date of this report unless other archiving requirements were included in the quote.

If there are any questions about the report or services performed during this project, please call Forest at (907) 562-2343. We will be happy to answer any questions or concerns which you may have.

Thank you for using SGS North America Inc. for your analytical services. We look forward to working with you again on any additional analytical needs.

Sincerely,
SGS North America Inc.

Stephen C. Ede
Alaska Division Technical Director

Case Narrative

SGS Client: **Environmental Mgmt Inc (EMI)**
SGS Project: **1133673**
Project Name/Site: **CMS Monofills**
Project Contact: **Larry Helgeson**

Refer to sample receipt form for information on sample condition.

Residual A (1133673001) PS

8270D - LOQs are elevated due to sample dilution. Sample analyzed at a dilution due to matrix.
8270D - Surrogate recovery is outside of QC criteria due to sample dilution.
300.0 - Sulfate - Sulfate was analyzed off of the SPLP extract. Sulfate results: 591 mg/L.

Residual B (1133673002) PS

8270D - LOQs are elevated due to sample dilution. Sample analyzed at a dilution due to matrix.
8270D - Surrogate recovery is outside of QC criteria due to sample dilution.
300.0 - Sulfate - Sulfate was analyzed off of the SPLP extract. Sulfate results: 520 mg/L.

Residual C (1133673003) PS

8270D - LOQs are elevated due to sample dilution. Sample analyzed at a dilution due to matrix.
8270D - Surrogate recovery is outside of QC criteria due to sample dilution.
300.0 - Sulfate - Sulfate was analyzed off of the SPLP extract. Sulfate results: 673 mg/L.

LCSD for HBN 1472973 [XXX/2964 (1168117) LCSD

8270D - LCS/LCSD RPD for pyridine and anitine does not meet QC criteria. These analytes were not detected above the LOQ in the associated samples.

1138227001MSD (1167786) MSD

6020 - Metals - MSD recoveries for several analytes were outside of acceptance criteria. Post digestion spike was successful.

*QC comments may be associated with the field samples found in this report. When applicable, comments will be applied to associated field samples.

Laboratory Qualifiers

Enclosed are the analytical results associated with the above work order. All results are intended to be used in their entirety and SGS is not responsible for use of less than the complete report. If you have any questions regarding this report, or if we can be of any other assistance, please contact your SGS Project Manager at 907-562-2343. All work is provided under SGS general terms and conditions (<http://www.sgs.com/terms_and_conditions.htm>), unless other written agreements have been accepted by both parties.

SGS maintains a formal Quality Assurance/Quality Control (QA/QC) program. A copy of our Quality Assurance Plan (QAP), which outlines this program, is available at your request. The laboratory certification numbers are AK00971 (DW Chemistry & Microbiology) & UST-005 (CS) for ADEC and 2944.01 for DOD ELAP/ISO17025 (RCRA methods: 1020A, 1311, 3010A, 3050B, 3520C, 3550C, 5030B, 5035B, 6020, 7470A, 7471B, 8021B, 8082A, 8260B, 8270D, 8270D-SIM, 9040B, 9045C, 9056A, 9060A, AK101 and AK102/103). Except as specifically noted, all statements and data in this report are in conformance to the provisions set forth by the SGS QAP and, when applicable, other regulatory authorities.

The following descriptors or qualifiers may be found in your report:

*	The analyte has exceeded allowable regulatory or control limits.
!	Surrogate out of control limits
B	Indicates the analyte is found in a blank associated with the sample.
CCV	Continuing Calibration Verification
CL	Control Limit
D	The analyte concentration is the result of a dilution.
DF	Dilution Factor
DL	Detection Limit (i.e., maximum method detection limit)
E	The analyte result is above the calibrated range.
F	Indicates value that is greater than or equal to the DL
GT	Greater Than
IB	Instrument Blank
ICV	Initial Calibration Verification
J	The quantitation is an estimation.
JL	The analyte was positively identified, but the quantitation is a low estimation.
LCS(D)	Laboratory Control Spike (Duplicate)
LOD	Limit of Detection (i.e., 2xDL)
LOQ	Limit of Quantitation (i.e., reporting or practical quantitation limit)
LT	Less Than
M	A matrix effect was present.
MB	Method Blank
MS(D)	Matrix Spike (Duplicate)
ND	Indicates the analyte is not detected.
Q	QC parameter out of acceptance range.
R	Rejected
RPD	Relative Percent Difference
U	Indicates the analyte was analyzed for but not detected.

Note Sample summaries which include a result for "Total Solids" have already been adjusted for moisture content. All DRO/RRO analyses are integrated per SOP.

SAMPLE RECEIPT FORM

Review Criteria:	Condition:	Comments/Action Taken:
Were custody seals intact? Note # & location, if applicable. **COC accompanied samples?**	Yes No (N/A) (Yes) No N/A	
Temperature blank compliant* (i.e., 0-6°C after CF)? ** Note: Exception permitted for chilled samples collected less than 2 hours ago.* Cooler ID: _____ @ _____ w/ Therm.ID: _____ Cooler ID: _____ @ _____ w/ Therm.ID: _____ Cooler ID: _____ @ _____ w/ Therm.ID: _____ Cooler ID: _____ @ _____ w/ Therm.ID: _____ Cooler ID: _____ @ _____ w/ Therm.ID: _____ *Note: If non-compliant, use form FS-0029 to document affected samples/analyses.* If samples are received without a temperature blank, the "cooler temperature" will be documented in lieu of the temperature blank & "COOLER TEMP" will be noted to the right. In cases where neither a temp blank nor cooler temp can be obtained, note "ambient" or "chilled." **If temperature(s) <0°C, were all sample containers ice free?**	Yes No (N/A) Yes No (N/A)	Ambient
Delivery method (specify all that apply): (Client) USPS Alert Courier C&D Delivery AK Air Lynden Carlile ERA PenAir FedEx UPS NAC Other: → *For WO# with airbills, was the WO# & airbill info recorded in the Front Counter eLog?*	Note ABN/ tracking # See Attached or (N/A) Yes No (N/A)	
→ For samples received with payment, note amount ($) and cash / check / CC (circle one) or note: (N/A) → For samples received in FBKS, ANCH staff will verify all criteria are reviewed.		SRF Initiated by: SLC N/A
Were samples received within hold time? *Note: Refer to form F-083 "Sample Guide" for hold time information.* **Do samples match COC*** (i.e., sample IDs, dates/times collected)? ** Note: Exception permitted if times differ <1hr; in that case, use times on COC.* **Were analyses requested unambiguous?**	(Yes) No N/A (Yes) No N/A (Yes) No N/A	
Were samples in good condition (no leaks/cracks/breakage)? **Packing material used** (specify all that apply): Bubble Wrap Separate plastic bags Vermiculite Other:	(Yes) No N/A	
Were all VOA vials free of headspace (i.e., bubbles ≤6 mm)? **Were all soil VOAs field extracted with MeOH+BFB?**	Yes No (N/A) Yes No (N/A)	
Were proper containers (type/mass/volume/preservative*) **used?** ** Note: Exception permitted for waters to be analyzed for metals.* **Were Trip Blanks** (i.e., VOAs, LL-Hg) in cooler with samples?	(Yes) No N/A Yes No (N/A)	
For special handling (e.g., "MI" or foreign soils, lab filter, limited volume, Ref Lab), **were bottles/paperwork flagged** (e.g., sticker)?	Yes No (N/A)	
For preserved waters (other than VOA vials, LL-Mercury or microbiological analyses), **was pH verified and compliant?** **If pH was adjusted, were bottles flagged** (i.e., stickers)?	Yes No (N/A) Yes No (N/A)	
For RUSH/SHORT Hold Time, were COC/Bottles flagged accordingly? Was Rush/Short HT email sent, if applicable?	Yes No (N/A)	
For SITE-SPECIFIC QC, e.g. BMS/BMSD/BDUP, were containers / paperwork flagged accordingly?	Yes No (N/A)	
For any question answered "No," has the PM been notified and the problem resolved (or paperwork put in their bin)?	Yes No (N/A)	SRF Completed by: SLC 8/8/13 PM = N/A
Was PEER REVIEW of *sample numbering/labeling completed?*	Yes No (N/A)	Peer Reviewed by: N/A
Additional notes (if applicable):		

Note to Client: Any "no" circled above indicates non-compliance with standard procedures and may impact data quality.

Background

The National Demolition Association

For more than two decades, the National Demolition Association has been a source of information about the demolition industry, offering its professional and experience-based insight to governmental regulators, and helping to ensure that environmentally responsible and safe practices are standard practice for the demolition industry.

As the recognized voice for the demolition industry, the National Demolition Association is often asked for information about topics of current focus, concern, and significance. This report has been prepared in response to requests from the U.S. Environmental Protection Agency for information about the character of demolition waste, methods by which it is managed, the quality of leachate from demolition landfills, associated environmental risks, and for the National Demolition Association's conclusions and recommendations regarding the type of regulation and control appropriate for demolition landfills.

Sierra Club vs. Browner

In settlement of a lawsuit brought by the Sierra Club, the U.S. EPA agreed to promulgate revised criteria for nonmunicipal solid waste facilities in the coming months. Demolition landfills which receive for disposal a very controlled and limited wastestream are one type of facility which could be subject to such regulations.

The EPA has requested the National Demolition Association to provide information that will help address the question of whether regulations similar to EPA's Sub-title D standards for municipal solid waste landfills are needed to ensure environmental protection for landfills serving the demolition industry – essentially to answer the question, are demolition wastes managed and disposed of responsibly?

National Demolition Association's Databases

For decades, the National Demolition Association has supported the environmentally responsible management of demolition wastes by the industry. National Demolition Association experience has led to it's firm belief that these efforts have resulted in safe management of demolition wastes. However, National Demolition Association's knowledge of the effectiveness of the industry's efforts is not the same as being able to demonstrate and document:

- What **materials** are being landfilled?
- What type of **regulations** apply to demolition landfills across the U.S.?
- What are the **characteristics of leachate** from demolition landfills?

In order to provide the best available base of information to address these questions, the National Demolition Association sought an independent third-party to perform the necessary research effort. The firm of Gershman, Brickner & Bratton, Inc. (GBB), recognized experts in the study and management of demolition waste, was retained to complete a nation-wide research program that would compile and review databases on the characteristics of demolition waste, applicable state regulations, and leachate characteristics. These research efforts and their resulting resource documents are identified in the table below.

Table 1: National Demolition Association Databases and Reports

Topic	Research Approach	Resource Developed
Characteristics of construction and demolition wastes	Complication of published reports and articles about the composition of materials delivered to demolition landfills for disposal	*C&D Waste Characterization Database, Volumes 1&2*, prepared for the National Demolition Association by GBB, February, 1994
Regulations governing design, operation, monitoring, and closure of demolition landfills	Survey of 50 states	*State Regulatory Database, Volumes 1&2*, prepared for the National Demolition Association by GBB, August, 1944
Characteristics of leachate from demolition landfills	Survey of 50 states, published reports and articles, records solicited from operating facilities	*C&D Waste Landfills Leachate Quality Data, Volumes 1&2*, prepared for the National Demolition Association by GBB, February, 1995
Analysis of collected leachate data	GBB evaluation of collected information	*Preliminary Report on Demofill Leachate Quality*, prepared for the National Demolition by GBB, February, 1995

The databases and technical reports developed through GBB's efforts are available through the NATIONAL DEMOLITION ASSOCIATION; more information about how to obtain these resource reports can be found on the last page of this document.

How does the Demolition Industry Manage Project Site and Segregate Waste Streams for Proper Handling?

What is demolition waste?

Before significant demolition activity begins, demolition contractors carefully inventory and isolate items which are know to be hazardous. Materials which are difficult to identify or which are suspected of potentially having hazardous characteristics are also isolated. Suspect materials are either identified or tested in order to select an appropriate disposal method. Marketable timbers, metals, fixtures, and other materials from demolition projects which have value for reuse or recycling are segregated and recovered. The demolition industry annually recycles millions of tons of concrete, steel, and brick.
As a result of these efforts to isolate hazardous items for separate disposal and to reclaim materials of value, the demolition wastes which are ultimately delivered to landfills comprise only a portion of all the material initially found at demolition project sites. This landfilled fraction is composed of materials which cannot be economically recovered and which do not require special disposal arrangements. Numerous composition studies show this landfilled fraction to be primarily a mixture of unrecyclable concrete, wood, glass, metals, roofing materials, plastics, and dirt, an inert material.

Pre-demolition Inspections

A first step for demolition projects includes a walk-through visual inspection that helps to identify any transformers, drums, liquids, tanks, or other items which will require special handling and/or testing. Site managers and crews are highly trained and drilled in the importance of identifying and isolating suspect materials. Many projects are begun only after a more formal site audit is performed by the site owner or a third party environmental consultant.

In addition, during the site inspection demolition contractors identify materials to be removed and sold for reuse or to be processed and recycled. This inspection process is also essential for the demolition contractor to identify any structural hazards, note any safety concerns and to determine the specific sequence that will be followed for the demolition activities.

Sequencing of Demolition Activities

Interior or partial demolition projects and an increasing number of total demolition projects are scheduled so that the removal of floor coverings, ceiling materials, interior walls, and other items occur in sequence before any structural demolition takes place. These steps maximize the efficiency and safety of the process and provide a further opportunity to inspect the waste materials as they are separately removed and readied for disposal.

Demolition contractors provide sophisticated safeguards for their businesses, employees, and projects by being experts in the applicable regulations for their projects: air quality, water quality, solid and hazardous waste, occupational safety, and noise, among others. The industry's standard practice entails careful assessment of project sites well in advance of demolition activities; specialized removal and disposal of potentially hazardous items; recycling of marketable equipment and extensive recycling of brick, concrete, and steel, along with growing efforts to recycle wood waste. The balance of materials from demolition project sites are landfilled.

Composition of Wastes Delivered to Demolition Landfills

The database compiled by GBB shows that the majority of wastes delivered to demolition landfills are made up of mixed concrete, wood, brick, rubble, metals (primarily ferrous), soil and fines, and smaller quantities of intermixed glass, plastics, textiles, and other materials.

The quantity and type of waste materials received by demolition landfills vary somewhat by the type of activity performed: site clearance, roadwork, excavation, building demolition, and construction/renovation. Some demolition landfills receive waste from all these types of activities; some accept only a more limited spectrum; for example, some accept wastes originating strictly from demolition operations. However, data from many sources shows a general materials profile for the wastes received at all studied demolition landfills, with wood waste dominating, followed by concrete and other rubble. Ferrous metals, glass, plastics, roofing materials, and other items comprise significantly smaller fractions of the mix.

The full waste composition database compiled by GBB is available from the National Demolition Association. This compilation of studies and investigations of demolition landfills across the U.S. shows a certain degree of uniformity in the categories of waste landfilled at these facilities, and the composition consists of a limited range of materials. In contrast, landfills for municipal solid waste (MSW-the aggregate wastestream from a community's commercial, residential, and industrial sources) and landfills for industrial waste disposal typically receive a very broad spectrum of waste types and quantities.

The waste characteristics of these facilities has a far higher organic fraction, and the generation of the incoming waste loads is from millions of untrained, often indifferent, casual generators. In contrast, demolition wastes originate from a highly specialized and trained industry, whose success in safeguarding the environment is evident both in the uniformity of composition found in the database search as well as in the historical absence of significant environmental problems associated with landfills that have accepted only demolition wastes.

How are demolition landfills currently regulated?

State Regulations

GBB's nationwide survey found that over 40 of the 50 states have differentiated regulations for demolition landfills. However, where the states have regulated demolition landfills, their regulatory approaches have generally reflected the comparatively inert character of the demolition wastestream, and demolition landfill requirements have been far less complex than the requirements the states have put in force for the management and disposal of municipal solid wastes and industrial wastes.

For the majority of states which do regulate demolition landfills, a significant portion of the regulations rely heavily on disclosure of the location of small volume disposal facilities and on the innocuous character of the wastestream to provide a sufficient safeguard for disposal sites. Commonly, small demolition disposal sites are required only to provide a registration or notification of operations and to maintain simple records of the quantity and/or origin of wastes disposed.

Most states which have adopted more formal permit or license requirements for demolition landfills have some form of groundwater monitoring requirement as well. GBB's analysis however, has found that these standards are often inadequate to document both background groundwater quality as well as a discernible identification of the effects of the monitored facilities.

What are the operating practices and design characteristics of a state-of-the-art landfill serving the demolition industry?

Based on the experience of the demolition industry, the National Demolition Association has identified an inventory of the operating practices and design characteristics that it considers to be representative of demolition landfill that reflects current industry standards. For many situations, these attributes would exceed the minimum existing regulatory requirements. However, they are viewed by the National Demolition Association as representing an industry guideline for prudent, environmentally responsible operations.

Table 2: Operating Practices and Design Characteristics for State-of-the-Art Demolition Landfills

Responsible, trained personnel	Appropriate supervision of facility operations; training requirements for all on-site employees
Routine Procedures and Protocols	Plan of Operations or Operations Manual; training in site safety/operational practices required of all staff
Defined Listing of Acceptable and Unacceptable Waste	Wastes allowable for receipt well defined; personnel trained in identification
Inspection of All Incoming Waste Loads	Required disclosure of waste type and source; visual inspection of material when delivered also when placed on working face
Isolation and Analysis of Suspect Materials	Requirements for and routine practice of isolation of suspect materials; documented procedures for identification, isolation,testing, and disposal of unacceptable and suspect wastes
Siting	Suitable site surface and subsurface conditions; Compatible with adjacent land uses
Leachate Containment	Capacity to contain leachate either through native soil conditions, compaction of native soils, or other containment system
Groundwater Monitoring	Upgradient (background) and downgradient groundwater monitoring for appropriate parameters,tested at least annually
Record Keeping	Maintenance of records of waste receipts and waste placements
Financial Assurance	Long-term funding for post-closure cover maintenance
Closure Plan	Design for installation and maintenance of final cover

These standards and practices provide an assurance that demolition landfills are repositories of only those wastes appropriate for disposal at these sites and the corresponding assurance that unacceptable materials are diverted to proper management alternatives; long-term monitoring of the environment; and assurance of permanent facility care.

Just as demolition contractors apply stringent controls to ensure that hazardous materials are separately removed from project sites and properly disposed, similarly, state-of-the-art demolition landfills must apply clear, consistent standards to define wastes acceptable for disposal. This is among the best, most effective means of environmental control for demolition facilities. Training for site operators and personnel, training and informational materials for haulers and facility users; rigorous screening of incoming loads; records of gate receipts and disposal placement all are hallmarks of facilities which follow National Demolition Association guidance. Such steps can ensure that the long-standing characterization of demolition waste as environmentally innocuous is well-founded.

What are the characteristics of leachate from demolition landfills?

The third database developed for the National Demolition Association by GBB entailed compilation and review of demolition landfill leachate monitoring records and other background documentation about the quality of leachate generated from demolition landfills across the United States.

Data from MSW Sites is not Representative of Demolition Landfills

GBB's 1994 research and assessment found that many of the existing reports and leachate data supposedly about "demolition landfills" are seriously flawed. Municipal solid waste has very different characteristics from demolition debris, and obviously, sizable deposits of municipal solid waste at facilities would skew the groundwater monitoring data considerably. Several sites classified as construction/demolition landfills (sites supposedly accepting only demolition and construction waste) were found to have accepted municipal solid waste for some period of time. It is suspected that many facilities were converted to construction/ demolition landfills rather than attempt to comply with contemporary regulations for municipal solid waste sites. Regardless of such facilities' present suitability for demolition waste disposal, leachate data from such dual purpose facilities cannot be used to validly characterize the effects of construction/demolition wastes.

Leachate Data from a State-of-the-Art Demolition Landfill

The research effort found excellent long-term leachate test documentation (more than 5 years) from a state-of-the-art demolition landfill operated in a major midwestern metropolitan area. Reports provided by this facility to its state regulators document leachate characteristics on a quarterly basis. Because the facility is lined and leachate is collected, the information is comprehensive.

The facility operator has concluded that the facility's waste receipts are characteristic of the mix of materials regularly received by demolition landfills, and the National Demolition Association considers the data from this facility to be the best current information representative of leachate characteristics for demolition landfills meeting industry standards.

Representative Leachate Data for Demolition Landfills

Tables 3 and 4 are excerpted from GBB's technical analysis of the leachate database. On Table 3, the first column identifies the National Drinking Water Standard's Maximum (allowable) Contaminant Levels (MCL). The second column lists the published range of leachate concentrations found for demolition landfills, including those for which the data is flawed by a past history of MSW disposal. The third column, headed "Potential Surrogate Range C&D Landfills," provides a calculated range -a surrogate- for the range of contaminant's in the demolition landfill leachate. This calculated range is based heavily on the record of analysis for the representative midwestern demolition landfill described above.

The table indicates that contaminant concentrations in leachate from a state-of-the-art demolition landfill, as represented by the "Potential Surrogate Range" values, would not exceed primary national drinking water standards.

Table 4 compares the representative values for demolition landfill leachate, the "Potential Surrogate Range" in column 3, with one source's published data and its estimates of leachate concentrations for MSW landfills. As is quickly evident in a scan of the table, for most listed parameters, the "Potential Surrogate Range" representative of demolition facilities shows values far below those found at MSW sites, often by at least an order of magnitude.

Of special note is the fact that the GBB database showed that lead is not a major component of demolition landfill leachate even with high lead paint content often found in older demolition projects. The U.S. EPA has recently taken these findings into account in development of a proposed disposal standard for lead-based paint contaminated debris.

On Table 4, sulfate, a substance that is essentially environmentally innocuous, is the one parameter for which there is an exception to the pattern of higher concentrations in MSW leachate. The higher sulfate concentrations estimated for demolition facilities are associated with the higher volumes of concrete and rubble disposed at demolition sites.

Table 3. Leachate Data Summary[1]

	MCL[2]	Published Range C&D Landfills[4]	Potential Surrogate Range C&D Landfills
Metals (mg/L)			
Arsenic	0.05	ND-0.12	<0.002-0.02

National Demolition Association Conclusions and Recommendations

National Demolition Association's development of nation-wide databases regarding demolition waste composition, state regulation of demolition landfills, and demolition landfill leachate characteristics was prompted by requests for the best available up-to-date information that could help guide development of federal and state regulations applying to demolition landfills. National Demolition Association has concluded that data representative of state-of-the-art demolition landfill leachate does exist and is the best information representative of industry impacts. The National Demolition Association's database and associated research effort should be considered by regulators as a comprehensive attempt to reconcile several different databases, documents and opinions on the use of published construction/demolition landfill leachate databases in the effort to help formulate regulatory policy.

National Demolition Association's waste characterization database documents that a vast majority of waste received by demolition landfills is relatively inert. Demolition wastes are predominantly a mixture of wood, concrete, brick, dirt, metals, roofing materials, glass, plastics and other non-recyclable wastes.

Some have suggested that demolition lanfills must meet EPA standards for Sub-title D municipal solid waste landfills, a view based in part on data regarding demolition landfill leachate quality from studies which pre-date National Demolition Association's 1994 review and database compilation. It cannot be overemphasized that the extensive National Demolition Association research effort found that landfills that used to be "old MSW dumps" or that have been the recipients of unchecked, unauthorized or illegal waste generate poor quality leachate. Unfortunately, the records for some of these sites are still being considered as part of the database being relied on to support the development of new, more stringent regulations for demolition facilities. However, as National Demolition Association's database shows, leachate from state-of-the-art demolition landfills and MSW landfills are not similar in concentration or composition, and thus should not demand similar regulatory regimes.

These findngs support National Demolition Association's conclusion that properly designed, well

maintained and operated demolition waste landfills are the most economical and environmentally sound method to manage that portion of the demolition industry's waste which cannot economically be recycled. National Demolition Association recommends that the standards and practices outlined in Table 2 be the basis for defining the manner in which demolition landfills can remain a viable and economic alternative for disposal of demolition wastes. In all cases, the National Demolition Association believes that the development of effective regulations for demolition landfills must begin with a clear definition of the materials which constitute "Acceptable Waste" for demolition landfill disposal. In addition, every facility must have an Operations Plan which includes provisions to effectively exclude unacceptable wastes and provide for their proper management.

National Demolition Association believes that just as the disposal of significant quantities of hazardous waste, batteries, waste oils, and other special wastes have been successfully reduced and/or eliminated from MSW landfills, yard waste composting sites, and waste-to-energy facilities, it is possible to work through demolition contractors, home builders, general contractors and other construction/demolition waste generators to eliminate inappropriate materials from demolition landfills.

In response to the challenge of handling the large amount of demolition debris generated in the United States in an environmentally safe manner, National Demolition Association members recycle millions of tons of waste annually, creating products for use in manufacturing, road building and maintenance, landscaping, nursery production, and more. However, not all wastes can be recycled, therefore, landfilling remains an integral, necessary component of the industry's appropriate waste management options. The demolition landfill is considered by the National Demolition Association to be a viable means of disposal for construction/demolition waste. For years, these facilities have accepted construction/demolition wastes and, when managed properly, pose no significant threat to the environment.

Databases, Reports, and Other Information

The databases and technical reports described in this document are available from the National Demolition Association for the nominal cost of reproduction.

- *C&D Waste Characterization Database, Volumes 1&2*, prepared for the National Demolition Association by GBB, February, 1994
- *State Regulatory Database, Volumes 1&2,* prepared for the National Demolition Association by GBB, August, 1994
- *C&D Waste Landfills Leachate Quality Data, Volumes 1&2,* prepared for the National Demolition Association by GBB, February, 1994

About the National Demolition Association

The size and experience of its membership have made the National Demolition Association of a driving force and voice for the demolition and recycling industry for nearly a quarter century. The National Demolition Association was formed in 1972 as a non-profit organization to foster communication between the public, governmental regulators and contractors engaged in the demolition industry. The National Demolition Association sponsors educational programs to increase public understanding of all aspects of the demolition industry, supports research efforts regarding issues of concern, and acts as an information clearinghouse for its members.

For copies of these documents or for additional information about the National Demolition Association or about the demolition industry, please call or write:

ATTACHMENT D – LETTERS OF SUPPORT

DiTomaso, Inc.

June 13, 2013

To Whom It May Concern:

Please accept this letter as our support to Central Recycling Services, (CRS), and Central Monofill Service in their effort to obtain a conditional use permit.

Our offices and warehouse are located at 601 Yakutat Street, directly adjacent to Central Recycling Services. We have been at this location since 1990 and a neighbor of CRS since they moved to their current location more than three years ago.

It has been our observation in the time (CRS) has been our neighbor that there has been no change in the quality of the area's environment. There has been no increase in excessive noise or odors, no change in bird or other pest presence, or any problem of debris and litter coming onto our property.

We would hope that the value, to the business community and the community at large, of the type of services (CRS) offers should be evident as a necessity and strongly urge the granting of the permit.

Very Sincerely,

Jeffrey Keim
Secretary/Treasurer

601 Yakutat St. Anchorage, Alaska 99501 (907) 276-8343 Fax (907) 278-8392

STATEWIDE SERVICES
- Auctioneers
- Real Estate Broker
- Liquidators
- Personal Property Appraisals

To Whom it may Concern:

I am writing in support of the Conditional Use Permit for which Central Monofill Service (CMS) and Central Recycling Services (CRS) have applied. My business has been located adjacent to the CRS facility for over three years, and my office is within 500 feet of the site where the bulk of the recycling is done. Trucks loaded with debris that might normally end up in the landfill enter the facility, and in the time we have been neighbors there have been no problems of any sort. Concerns of noise, odors and blowing debris that attracts birds is unfounded. We have observed none of these issues. The services of CMS and CRS are of tremendous value to the community and to the state of Alaska. The granting of the Conditional Use Permit will allow these businesses to grow and expand and add to the economic vitality of the city and the Ship Creek industrial area. The benefits these businesses bring to the area far outweigh the perceived fears and concerns of future neighbors. It is my belief that they will prove to be baseless.

Ron Alleva,
President

June 11, 2013

To whom this may concern,

I am writing in support of Central Recycling Services plan to build a new monofill. I live in Salcha, Alaska located close to Fairbanks, Alaska and near Central Recycling Services monofill in Salcha, Alaska. As a neighbor, Central Recycling Services has made it so that living next to the monofill is, without a doubt, not a nuisance. From Central Recycling Services informing me when needed, keeping a clean area, and always being considerate of their surrounding and my land, I feel as though the monofill is not even there. In conclusion, the constrution of the monofill has not affected my home or the land around it in anyway, and I find that because of Central Recycling Services professional techniques and work ethic that it will be the same with the development of their new monofill.

If you have any questions or concerns please feel free to contact me.

Wesley Cullip

Dear Ms. Susan Lee

My name is Silvia Moore and I am writing this letter in support of Shane Durand and his company.

I, Silvia Moore would like to make a public comment on the Central Monofill Services proposed Monofill site along the Glenn Highway.

I am the next doo neighbor to the Central Monofill Services site in Salcha, Alaska. Our driveway goes through the middle of their Monofill site. Prior to development of the Salcha property, we had concerns about traffic, noise and odors from the Monofill site.

Shane Durand and his employees have gone out of their way to address the concerns of the neighborhood. After a season of operations I am happy to be able to say things have been much better than we could have expected. Traffic has been minimal and the trucks have been more than considerate of local residents. We have had no issues with odors or debris blowing around from the site. Equipment has only operated on site during daytime hours as required and in general this operation is out of sight and out of mind.

Also some neighbors, the local school and I have directly experienced Shane Durand's kindness and helpfulness. This operation is one of the neatest ones I have ever seen

I don't believe that you will have any regrets issuing permits to Central Monofill Services.

Please contact me at: 907 488-3831 if you have any further questions.

Sincerely,

Silvia Moore

Mrs. Moore

To whom it may concern: May 31, 2013

I would like to provide my support to Central Monofill Service, (CMS) and Central Recycling Services (CRS) and their application for a Conditional Use Permit. My business, Bob's Services Inc, is located directly adjacent to the C RS recycle facility in Anchorage. My office is within 500' of their operations. We have been neighbors now for over three years and I can report that we have no issues what so ever with their operations. Any concerns of noise, odors, blowing debris, dust and birds have never been an issue and no incidents with any of those concerns. The services CRS and CMS bring to Alaska we feel are highly needed and the granting of the Conditional Use Permit will allow their business to grow and expand, and in the short and long term be very beneficial to the State of Alaska. I can attest from experience that perceived fears and concerns of their operations have never been an issue with us as their neighbor and will not be an issue or problem.

Sincerely,

Bill Brown
President
Bob's Services Inc

May 31, 2013

To whom it may concern:

I am writing this letter in full support of **Central Recycling Services** and **Central Monofill Service** and their application for a Conditional Use Permit. Our offices and warehouse have been located at 2600 Railroad Avenue in Anchorage for more than 20 years. CRS Recycle is literally down the street from our offices and their trucks and their customers pass by our front door several times daily. We cannot recall one instance since CRS first moved in and opened for business in this location where we have had any issues with them as our neighbor or any reason for concern with their operations.

Central Recycling Services has diligently maintained their properties and the contents thereon in an exceptional manner. CRS continues to take an active role in policing and maintaining the roadways surrounding our businesses as do the rest of our neighbors. Their operations have not produced excessive noises or odors and they do a great job of organizing and separating the various materials brought in for recycle to their property. This is a model business providing a much needed service to the Alaskan community, which was barely conceived as feasible a dozen years ago.

It is our contention that the State of Alaska and its many communities will be better served with the granting of the Conditional Use Permit being sought by Central Recyclying Service and Central Monofil Service. Anything short of a full approval would be undeserved.

Should you have any questions concerning this letter, please contact the undersigned at (907) 272-7713.

Sincerely,

HICKEL CONSTRUCTION & ENGINEERING, INC.

Peter J. Hickel, President

CC: FILE/VEH

As a resident of Alaska who cares about our people, environment , and working in the Engineering field as the State Materials Engineer for the Department of Transportation & Public Facilities--I would like to submit a formal comment regarding the conditional use permit application for Central Monofill Services operated by Central Recycling Services, per MSB 17.60, requesting to operate a monofill for the disposal of inert material within the Matanuska-Susitna Borough.

Per the application I understand that;

The inert debris will primarily be non-hazardous shredded residual nonrecyclable waste material from construction and demolition waste and will also accept Regulated Asbestos Containing Material (RACM) and Non-RACM will be accepted at the site. The proposed site is located on MSB Tax Parcels: 17N02E18C010 (2840 S. Glenn Highway) and 17N02E19B006 (2560 S. Glenn Highway; within Township 17 North, Range 2 East, Sections 18 and 19, Seward Meridian. Applicant: Central Monofill Services.

Working in the Engineering field with specific expertise in construction materials, I can say I have a good grasp of most all the issues surrounding monofills and recycling of materials. The question of having a recycling operation in your community, monofill or not, is highly dependent on who is in responsible charge of its daily operations as well as the reputation of the company tasked in the governance of these types of endeavors because if properly permitted, maintained, and operated a monofill and recycling center can become an asset to the surrounding community its supports. I pass this on having seen the revival of Anchorage's Glass Recycling Program, which would not have been possible without the hard fought work of Shane Durand with Central Recycling Services , who along with ALPAR came to AKDOT&PF in hopes of finding a use for the glass containers waste stream entering our Landfill. Shane at Central Recycling Services, ALPAR, and my office worked together to educate engineers that ultimately drafted a statewide crushed glass construction material specification for AKDOT&PF projects, a specification that would strengthen our roads at that same time strengthen our State. Each year new research is published on transportation construction materials that professes the benefits of using recycled materials to construct long lasting and durable infrastructure by using product once thought only best suited for landfill waste. Recently, there has been discussions, presentation, and research on the use of non-hazardous fines produced as a by-product from recycled waste to construct durable embankments for highways and roads. This material is similar to the type of materials seen in most monofill operations today. I am not saying that the Department of Transportation is anytime soon going to be using this material because the research has just begun, but it does highlight an important issue of something we once thought was only waste can, or could be, engineered to economically be turned into valuable construction materials.

As the State Materials Engineer my job is to sample & test materials and of course define their quality and in doing so I have come to know quality when I find it. Having said that, and having personally worked with Central Recycling Services and Shane Durand who oversees daily operations at the Recycling Center in Anchorage, I have at every turn encountered Quality in the company and person, respectively. ! personally believe, if Matanuska-Susitna Borough permits Central Recycling Services to operate a monofill and recycling center in the Matanuska-Susitna Borough its operations and the services provided by Central Recycling will quickly become a valued asset and highly praised member or your community. Central Recycling Services and Shane Durand are bringing Alaska information and services long provided in the lower 48. and if allowed will work to improve their new community one piece of recycled materials at a time. They have consistently clean operations, follow the strictest of standards, and have shown, at times, to go beyond the minimums even at the expense of profits-- all the time knowing other ventures could prove more profitable--but they choose to continue their commitment to clean recycling, I think, it's simply because they find value in it. Thank You for considering my comments, and no matter the outcome, if anyone at the Borough ever wants to talk about my favorite subject "construction materials" feel free to call any time. And in closing I want to wish the Matanuska-Susitna Borough all the best in the coming future.

Warm Regards

Michael San Angelo P.E.

State Materials Engineer, AKDOT&PF

907-269-6234

ATTACHMENT E – JURISDICTIONAL DETERMINATION

DEPARTMENT OF THE ARMY
U.S. ARMY ENGINEER DISTRICT, ALASKA
ANCHORAGE FIELD OFFICE CEPOA-RD-SA
1600 A STREET SUITE 110
ANCHORAGE, ALASKA 99501-5146

REPLY TO ATTENTION OF:

Regulatory Division
POA-2013-305

JUL 25 2013

Central Monofill Services
Attention: Shane Durand
311 North Sitka Street
Anchorage, Alaska 99501

Dear Mr. Durand:

This letter responds to your May 24, 2013, request for a Department of the Army (DA) jurisdictional determination for your proposed Palmer Monofill Site. It has been assigned number POA-2013-305, Matanuska River, which should be referred to in all correspondence with us. The project site is located within Section 18, T. 17 N., R. 2 E., Seward Meridian; USGS Quad Map Anchorage C-6; Latitude 61.5577º N., Longitude 149.1749º W.; Matanuska-Susitna Borough; near Palmer, Alaska.

Based on our review of the information you provided and resources available to us, we have determined the subject property does not contain waters of the United States (U.S.) under Corps jurisdiction. Therefore, a DA permit is not required. A copy of the Approved Jurisdictional Determination form is available at: www.poa.usace.army.mil/Missions/Regulatory/JurisdictionalDeterminations.aspx under the above file number.

This approved jurisdictional determination is valid for a period of five (5) years from the date of this letter, unless new information supporting a revision is provided to us before the expiration date.

Enclosed is a Notification of Administrative Appeal Options and Process and Request for Appeal form regarding this approved jurisdictional determination (see section labeled "Approved Jurisdictional Determination").

Section 404 of the Clean Water Act requires that a DA permit be obtained for the placement or discharge of dredged and/or fill material into waters of the U.S., including jurisdictional wetlands (33 U.S.C. 1344). The Corps defines wetlands as those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions.

Section 10 of the Rivers and Harbors Act of 1899 requires that a DA permit be obtained for structures or work in or affecting navigable waters of the U.S. (33 U.S.C. 403). Section 10 waters are those waters subject to the ebb and flow of the tide shoreward to the mean high water mark, and/or other waters identified by the Alaska District.

Nothing in this letter excuses you from compliance with other Federal, State, or local statutes, ordinances, or regulations.

Please contact me via email at Steve.D.Lindamood@usace.army.mil, by mail at the address above, by phone at (907) 753-2796, or toll free from within Alaska at (800) 478-2712, if you have questions.

Sincerely,

Steve Lindamood
Project Manager

APPROVED JURISDICTIONAL DETERMINATION FORM
U.S. Army Corps of Engineers

This form should be completed by following the instructions provided in Section IV of the JD Form Instructional Guidebook.

SECTION I: BACKGROUND INFORMATION

A. REPORT COMPLETION DATE FOR APPROVED JURISDICTIONAL DETERMINATION (JD): 24 July 2013

B. DISTRICT OFFICE, FILE NAME, AND NUMBER: Alaska District, POA-CEPOA-RD-SA-POA-2013-305

C. PROJECT LOCATION AND BACKGROUND INFORMATION:
State: Alaska Borough: Matanuska-Susitna City: Palmer
Center coordinates of site (lat/long in degree decimal format, NAD-83): Lat. 61.5577° N, Long. 149.1749° W;
Universal Transverse Mercator: N/A; Within section(s) 18, T. 17 N., R. 2 E., Seward Meridian
Name of nearest water body: Matanuska River
Name of nearest Traditional Navigable Water (TNW) into which the aquatic resource flows: N/A - Uplands
Name of watershed or Hydrologic Unit Code (HUC): N/A
☒ Check if map/diagram of review area and/or potential jurisdictional areas is/are available upon request.
☐ Check if other sites (e.g., offsite mitigation sites, disposal sites, etc…) are associated with this action and are recorded on a different JD form.

D. REVIEW PERFORMED FOR SITE EVALUATION (CHECK ALL THAT APPLY):
☒ Office (Desk) Determination. Date: 24 July 2013
☐ Field Determination. Date(s):

SECTION II: SUMMARY OF FINDINGS

A. RHA SECTION 10 DETERMINATION OF JURISDICTION.

There **Are no** "*navigable waters of the U.S.*" within Rivers and Harbors Act (RHA) jurisdiction (as defined by 33 CFR part 329) in the review area. [***Required***]
☐ Waters subject to the ebb and flow of the tide.
☐ Waters are presently used, or have been used in the past, or may be susceptible for use to transport interstate or foreign commerce. Explain:

B. CWA SECTION 404 DETERMINATION OF JURISDICTION.

There **Are no** "*waters of the U.S.*" within Clean Water Act (CWA) jurisdiction (as defined by 33 CFR part 328) in the review area. [***Required***]

1. **Waters of the U.S.**
   a. **Indicate presence of waters of U.S. in review area (check all that apply):** [1]
      ☐ TNWs, including territorial seas
      ☐ Wetlands adjacent to TNWs
      ☐ Relatively permanent waters[2] (RPWs) that flow directly or indirectly into TNWs
      ☐ Non-RPWs that flow directly or indirectly into TNWs
      ☐ Wetlands directly abutting RPWs that flow directly or indirectly into TNWs
      ☐ Wetlands adjacent to but not directly abutting RPWs that flow directly or indirectly into TNWs
      ☐ Wetlands adjacent to non-RPWs that flow directly or indirectly into TNWs
      ☐ Impoundments of jurisdictional waters
      ☐ Isolated (interstate or intrastate) waters, including isolated wetlands

   b. **Identify (estimate) size of waters of the U.S. in the review area:**
      Non-wetland waters: linear feet: width (ft) and/or acres
      Wetlands: acres

   c. **Limits (boundaries) of jurisdiction** based on: **Pick List**
      Elevation of established OHWM (if known):

2. **Non-regulated waters/wetlands (check if applicable):**[3]
   ☐ Potentially jurisdictional waters and/or wetlands were assessed within the review area and determined to be not jurisdictional. Explain:

[1] Boxes checked below shall be supported by completing the appropriate sections in Section III below.
[2] For purposes of this form, an RPW is defined as a tributary that is not a TNW and that typically flows year-round or has continuous flow at least "seasonally" (e.g., typically 3 months).
[3] Supporting documentation is presented in Section III.F.

SECTION III: CWA ANALYSIS

A. TNWs AND WETLANDS ADJACENT TO TNWs

The agencies will assert jurisdiction over TNWs and wetlands adjacent to TNWs. If the aquatic resource is a TNW, complete Section III.A.1 and Section III.D.1. only; if the aquatic resource is a wetland adjacent to a TNW, complete Sections III.A.1 and 2 and Section III.D.1.; otherwise, see Section III.B below.

1. **TNW**
   Identify TNW:

   Summarize rationale supporting determination:

2. **Wetland adjacent to TNW**
   Summarize rationale supporting conclusion that wetland is "adjacent":

B. CHARACTERISTICS OF TRIBUTARY (THAT IS NOT A TNW) AND ITS ADJACENT WETLANDS (IF ANY):

This section summarizes information regarding characteristics of the tributary and its adjacent wetlands, if any, and it helps determine whether or not the standards for jurisdiction established under *Rapanos* have been met.

The agencies will assert jurisdiction over non-navigable tributaries of TNWs where the tributaries are "relatively permanent waters" (RPWs), i.e. tributaries that typically flow year-round or have continuous flow at least seasonally (e.g., typically 3 months). A wetland that directly abuts an RPW is also jurisdictional. If the aquatic resource is not a TNW, but has year-round (perennial) flow, skip to Section III.D.2. If the aquatic resource is a wetland directly abutting a tributary with perennial flow, fill out Section III.D.2 and Section III.D.4.

A wetland that is adjacent to but that does not directly abut an RPW requires a significant nexus evaluation. Corps districts and EPA regions will include in the record any available information that documents the existence of a significant nexus between a relatively permanent tributary that is not perennial (and its adjacent wetlands if any) and a traditional navigable water, even though a significant nexus finding is not required as a matter of law.

If the water body[4] is not an RPW, or a wetland directly abutting an RPW, a JD will require additional data to determine if the water body has a significant nexus with a TNW. If the tributary has adjacent wetlands, the significant nexus evaluation must consider the tributary in combination with all of its adjacent wetlands. This significant nexus evaluation that combines, for analytical purposes, the tributary and all of its adjacent wetlands is used whether the review area identified in the JD request is the tributary, or its adjacent wetlands, or both. If the JD covers a tributary with adjacent wetlands, complete Section III.B.1 for the tributary, Section III.B.2 for any onsite wetlands, and Section III.B.3 for all wetlands adjacent to that tributary, both onsite and offsite. The determination whether a significant nexus exists is determined in Section III.C below.

1. **Characteristics of non-TNWs that flow directly or indirectly into TNW**

   (i) **General Area Conditions:**
   Watershed size: **Pick List**
   Drainage area: **Pick List**
   Average annual rainfall: inches
   Average annual snowfall: inches

   (ii) **Physical Characteristics:**
   (a) Relationship with TNW:
   ☐ Tributary flows directly into TNW.
   ☐ Tributary flows through **Pick List** tributaries before entering TNW.

   Project waters are **Pick List** river miles from TNW.
   Project waters are **Pick List** river miles from RPW.
   Project waters are **Pick List** aerial (straight) miles from TNW.
   Project waters are **Pick List** aerial (straight) miles from RPW.
   Project waters cross or serve as state boundaries. Explain:

   Identify flow route to TNW[5]:
   Tributary stream order, if known:

[4] Note that the Instructional Guidebook contains additional information regarding swales, ditches, washes, and erosional features generally and in the arid West.
[5] Flow route can be described by identifying, e.g., tributary a, which flows through the review area, to flow into tributary b, which then flows into TNW.

(b) General Tributary Characteristics (check all that apply):
Tributary is: ☐ Natural
☐ Artificial (man-made). Explain:
☐ Manipulated (man-altered). Explain:

Tributary properties with respect to top of bank (estimate):
Average width: feet
Average depth: feet
Average side slopes: **Pick List**

Primary tributary substrate composition (check all that apply):
☐ Silts ☐ Sands ☐ Concrete
☐ Cobbles ☐ Gravel ☐ Muck
☐ Bedrock ☐ Vegetation. Type/% cover:
☐ Other. Explain:

Tributary condition/stability [e.g., highly eroding, sloughing banks]. Explain:
Presence of run/riffle/pool complexes. Explain:
Tributary geometry: **Pick List**
Tributary gradient (approximate average slope): %

(c) Flow:
Tributary provides for: **Pick List**
Estimate average number of flow events in review area/year: **Pick List**
Describe flow regime:
Other information on duration and volume:
Surface flow is: **Pick List**. Characteristics:
Subsurface flow: **Pick List**. Explain findings:
☐ Dye (or other) test performed:

Tributary has (check all that apply):
☐ Bed and banks
☐ OHWM[6] (check all indicators that apply):
☐ clear, natural line impressed on the bank ☐ the presence of litter and debris
☐ changes in the character of soil ☐ destruction of terrestrial vegetation
☐ shelving ☐ the presence of wrack line
☐ vegetation matted down, bent, or absent ☐ sediment sorting
☐ leaf litter disturbed or washed away ☐ scour
☐ sediment deposition ☐ multiple observed or predicted flow events
☐ water staining ☐ abrupt change in plant community
☐ other (list):
☐ Discontinuous OHWM.[7] Explain:

If factors other than the OHWM were used to determine lateral extent of CWA jurisdiction (check all that apply):
☐ High Tide Line indicated by: ☐ Mean High Water Mark indicated by:
☐ oil or scum line along shore objects ☐ survey to available datum;
☐ fine shell or debris deposits (foreshore) ☐ physical markings;
☐ physical markings/characteristics ☐ vegetation lines/changes in vegetation types.
☐ tidal gauges
☐ other (list):

(iii) Chemical Characteristics:
Characterize tributary (e.g., water color is clear, discolored, oily film; water quality; general watershed characteristics, etc.).
Explain:
Identify specific pollutants, if known:

[6]A natural or man-made discontinuity in the OHWM does not necessarily sever jurisdiction (e.g., where the stream temporarily flows underground, or where the OHWM has been removed by development or agricultural practices). Where there is a break in the OHWM that is unrelated to the water body's flow regime (e.g., flow over a rock outcrop or through a culvert), the agencies will look for indicators of flow above and below the break.
[7]Ibid.

(iv) Biological Characteristics. Channel supports (check all that apply):
- ☐ Riparian corridor. Characteristics (type, average width):
- ☐ Wetland fringe. Characteristics:
- ☐ Habitat for:
  - ☐ Federally Listed species. Explain findings:
  - ☐ Fish/spawn areas. Explain findings:
  - ☐ Other environmentally-sensitive species. Explain findings:
  - ☐ Aquatic/wildlife diversity. Explain findings:

2. Characteristics of wetlands adjacent to non-TNW that flow directly or indirectly into TNW

(i) Physical Characteristics:

(a) General Wetland Characteristics:
Properties:
Wetland size: acres
Wetland type. Explain:
Wetland quality. Explain:
Project wetlands cross or serve as state boundaries. Explain:

(b) General Flow Relationship with Non-TNW:
Flow is: **Pick List**. Explain:

Surface flow is: **Pick List**
Characteristics:

Subsurface flow: **Pick List**. Explain findings:
- ☐ Dye (or other) test performed:

(c) Wetland Adjacency Determination with Non-TNW:
- ☐ Directly abutting
- ☐ Not directly abutting
  - ☐ Discrete wetland hydrologic connection. Explain:
  - ☐ Ecological connection. Explain:
  - ☐ Separated by berm/barrier. Explain:

(d) Proximity (Relationship) to TNW
Project wetlands are **Pick List** river miles from TNW.
Project waters are **Pick List** aerial (straight) miles from TNW.
Flow is from: **Pick List.**
Estimate approximate location of wetland as within the **Pick List** floodplain.

(ii) Chemical Characteristics:
Characterize wetland system (e.g., water color is clear, brown, oil film on surface; water quality; general watershed characteristics; etc.). Explain:
Identify specific pollutants, if known:

(iii) Biological Characteristics. Wetland supports (check all that apply):
- ☐ Riparian buffer. Characteristics (type, average width):
- ☐ Vegetation type/percent cover. Explain:
- ☐ Habitat for:
  - ☐ Federally Listed species. Explain findings:
  - ☐ Fish/spawn areas. Explain findings:
  - ☐ Other environmentally-sensitive species. Explain findings:
  - ☐ Aquatic/wildlife diversity. Explain findings:

3. Characteristics of all wetlands adjacent to the tributary (if any)
All wetland(s) being considered in the cumulative analysis: **Pick List**
Approximately ( ) acres in total are being considered in the cumulative analysis.

For each wetland, specify the following:

Directly abuts? (Y/N)	Size (in acres)	Directly abuts? (Y/N)	Size (in acres)

Summarize overall biological, chemical and physical functions being performed:

C. SIGNIFICANT NEXUS DETERMINATION

A significant nexus analysis will assess the flow characteristics and functions of the tributary itself and the functions performed by any wetlands adjacent to the tributary to determine if they significantly affect the chemical, physical, and biological integrity of a TNW. For each of the following situations, a significant nexus exists if the tributary, in combination with all of its adjacent wetlands, has more than a speculative or insubstantial effect on the chemical, physical and/or biological integrity of a TNW. Considerations when evaluating significant nexus include, but are not limited to the volume, duration, and frequency of the flow of water in the tributary and its proximity to a TNW, and the functions performed by the tributary and all its adjacent wetlands. It is not appropriate to determine significant nexus based solely on any specific threshold of distance (e.g. between a tributary and its adjacent wetland or between a tributary and the TNW). Similarly, the fact an adjacent wetland lies within or outside of a floodplain is not solely determinative of significant nexus.

Draw connections between the features documented and the effects on the TNW, as identified in the *Rapanos* Guidance and discussed in the Instructional Guidebook. Factors to consider include, for example:

- Does the tributary, in combination with its adjacent wetlands (if any), have the capacity to carry pollutants or flood waters to TNWs, or to reduce the amount of pollutants or flood waters reaching a TNW?
- Does the tributary, in combination with its adjacent wetlands (if any), provide habitat and lifecycle support functions for fish and other species, such as feeding, nesting, spawning, or rearing young for species that are present in the TNW?
- Does the tributary, in combination with its adjacent wetlands (if any), have the capacity to transfer nutrients and organic carbon that support downstream foodwebs?
- Does the tributary, in combination with its adjacent wetlands (if any), have other relationships to the physical, chemical, or biological integrity of the TNW?

Note: the above list of considerations is not inclusive and other functions observed or known to occur should be documented below:

1. **Significant nexus findings for non-RPW that has no adjacent wetlands and flows directly or indirectly into TNWs.** Explain findings of presence or absence of significant nexus below, based on the tributary itself, then go to Section III.D:

2. **Significant nexus findings for non-RPW and its adjacent wetlands, where the non-RPW flows directly or indirectly into TNWs.** Explain findings of presence or absence of significant nexus below, based on the tributary in combination with all of its adjacent wetlands, then go to Section III.D:

3. **Significant nexus findings for wetlands adjacent to an RPW but that do not directly abut the RPW.** Explain findings of presence or absence of significant nexus below, based on the tributary in combination with all of its adjacent wetlands, then go to Section III.D:

D. DETERMINATIONS OF JURISDICTIONAL FINDINGS. THE SUBJECT WATERS/WETLANDS ARE (CHECK ALL THAT APPLY):

1. **TNWs and Adjacent Wetlands.** Check all that apply and provide size estimates in review area:
   - ☐ TNWs: linear feet width (ft), Or, acres.
   - ☐ Wetlands adjacent to TNWs: acres.

2. **RPWs that flow directly or indirectly into TNWs.**
   - ☐ Tributaries of TNWs where tributaries typically flow year-round are jurisdictional. Provide data and rationale indicating that tributary is perennial:
   - ☐ Tributaries of TNW where tributaries have continuous flow "seasonally" (e.g., typically three months each year) are jurisdictional. Data supporting this conclusion is provided at Section III.B. Provide rationale indicating that tributary flows seasonally:

Provide estimates for jurisdictional waters in the review area (check all that apply):
- ☐ Tributary waters: linear feet width (ft)
- ☐ Other non-wetland waters: acres
  Identify type(s) of waters:

3. **Non-RPWs[8] that flow directly or indirectly into TNWs.**
   ☐ Water body that is not a TNW or an RPW, but flows directly or indirectly into a TNW, and it has a significant nexus with a TNW is jurisdictional. Data supporting this conclusion is provided at Section III.C.

   Provide estimates for jurisdictional waters within the review area (check all that apply):
   - ☐ Tributary waters: linear feet width (ft).
   - ☐ Other non-wetland waters: acres
     Identify type(s) of waters:

4. **Wetlands directly abutting an RPW that flow directly or indirectly into TNWs.**
   ☐ Wetlands directly abut RPW and thus are jurisdictional as adjacent wetlands.
   - ☐ Wetlands directly abutting an RPW where tributaries typically flow year-round. Provide data and rationale indicating that tributary is perennial in Section III.D.2, above. Provide rationale indicating that wetland is directly abutting an RPW:

   - ☐ Wetlands directly abutting an RPW where tributaries typically flow "seasonally." Provide data indicating that tributary is seasonal in Section III.B and rationale in Section III.D.2, above. Provide rationale indicating that wetland is directly abutting an RPW:

   Provide acreage estimates for jurisdictional wetlands in the review area: acres

5. **Wetlands adjacent to but not directly abutting an RPW that flow directly or indirectly into TNWs.**
   ☐ Wetlands that do not directly abut an RPW, but when considered in combination with the tributary to which they are adjacent and with similarly situated adjacent wetlands, have a significant nexus with a TNW are jurisidictional. Data supporting this conclusion is provided at Section III.C.

   Provide acreage estimates for jurisdictional wetlands in the review area: acres

6. **Wetlands adjacent to non-RPWs that flow directly or indirectly into TNWs.**
   ☐ Wetlands adjacent to such waters, and have when considered in combination with the tributary to which they are adjacent and with similarly situated adjacent wetlands, have a significant nexus with a TNW are jurisdictional. Data supporting this conclusion is provided at Section III.C.

   Provide estimates for jurisdictional wetlands in the review area: acres

7. **Impoundments of jurisdictional waters.[9]**
   As a general rule, the impoundment of a jurisdictional tributary remains jurisdictional.
   - ☐ Demonstrate that impoundment was created from "waters of the U.S.," or
   - ☐ Demonstrate that water meets the criteria for one of the categories presented above (1-6), or
   - ☐ Demonstrate that water is isolated with a nexus to commerce (see E below).

E. ISOLATED [INTERSTATE OR INTRA-STATE] WATERS, INCLUDING ISOLATED WETLANDS, THE USE, DEGRADATION OR DESTRUCTION OF WHICH COULD AFFECT INTERSTATE COMMERCE, INCLUDING ANY SUCH WATERS (CHECK ALL THAT APPLY):[10]
- ☐ which are or could be used by interstate or foreign travelers for recreational or other purposes.
- ☐ from which fish or shellfish are or could be taken and sold in interstate or foreign commerce.
- ☐ which are or could be used for industrial purposes by industries in interstate commerce.
- ☐ Interstate isolated waters. Explain:
- ☐ Other factors. Explain:

Identify water body and summarize rationale supporting determination:

---

[8] See Footnote # 3.
[9] To complete the analysis refer to the key in Section III.D.6 of the Instructional Guidebook.
[10] **Prior to asserting or declining CWA jurisdiction based solely on this category, Corps Districts will elevate the action to Corps and EPA HQ for review consistent with the process described in the Corps/EPA *Memorandum Regarding CWA Act Jurisdiction Following Rapanos.***

Provide estimates for jurisdictional waters in the review area (check all that apply):
☐ Tributary waters: linear feet width (ft)
☐ Other non-wetland waters: acres
Identify type(s) of waters:
☐ Wetlands: acres

F. NON-JURISDICTIONAL WATERS, INCLUDING WETLANDS (CHECK ALL THAT APPLY):
☐ If potential wetlands were assessed within the review area, these areas did not meet the criteria in the 1987 Corps of Engineers Wetland Delineation Manual and/or appropriate Regional Supplements.
☐ Review area included isolated waters with no substantial nexus to interstate (or foreign) commerce.
☐ Prior to the Jan 2001 Supreme Court decision in "*SWANCC*," the review area would have been regulated based solely on the "Migratory Bird Rule" (MBR).
☐ Waters do not meet the "Significant Nexus" standard, where such a finding is required for jurisdiction. Explain:
☐ Other: (explain, if not covered above):

Provide acreage estimates for non-jurisdictional waters in the review area, where the sole potential basis of jurisdiction is the MBR factors (i.e., presence of migratory birds, presence of endangered species, use of water for irrigated agriculture), using best professional judgment (check all that apply):
☐ Non-wetland waters (i.e., rivers, streams): linear feet width (ft).
☐ Lakes/ponds: acres.
☐ Other non-wetland waters: acres. List type of aquatic resource:
☐ Wetlands: acres.

Provide acreage estimates for non-jurisdictional waters in the review area that do not meet the "Significant Nexus" standard, where such a finding is required for jurisdiction (check all that apply):
☐ Non-wetland waters (i.e., rivers, streams): linear feet, width (ft).
☐ Lakes/ponds: acres.
☐ Other non-wetland waters: acres. List type of aquatic resource:
☐ Wetlands: acres.

SECTION IV: DATA SOURCES.

A. SUPPORTING DATA. Data reviewed for JD (check all that apply - checked items shall be included in case file and, where checked and requested, appropriately reference sources below):
☒ Maps, plans, plots or plat submitted by or on behalf of the applicant/consultant: **Project Site Map**
☐ Data sheets prepared/submitted by or on behalf of the applicant/consultant.
☐ Office concurs with data sheets/delineation report.
☐ Office does not concur with data sheets/delineation report
☐ Data sheets prepared by the Corps:
☐ Corps navigable waters' study:
☐ U.S. Geological Survey Hydrologic Atlas:
☐ USGS NHD data
☐ USGS 8 and 12 digit HUC maps
☐ Alaska District's Approved List of Navigable Waters
☒ U.S. Geological Survey map(s). Cite scale & quad name: **Anchorage C-6, Topographic Map**
☒ USDA Natural Resources Conservation Service Soil Survey. Citation: **Knik silt loam and Yensus silt loam**
☒ National wetlands inventory map(s). Cite name: **NWI Wetland Map**
☐ State/Local wetland inventory map(s):
☐ FEMA/FIRM maps:
☐ 100-year Floodplain Elevation is: (National Geodectic Vertical Datum of 1929)
☒ Photographs: ☐ Aerial (Name & Date):
or ☒ Other (Name & Date): **2011 Google Earth Pro Satellite Imagery**

RE: PENETRATION TESTING SUMMARY LETTER

Jay,

Per your request, Northern Geotechnical Engineering, Inc. d.b.a. Terra Firma Testing has prepared this summary letter to provide the mechanical properties of the materials for your project. A detailed calculation of the test data collected and the associated engineering conclusions are included in this letter.

Three penetration tests were conducted similar to California Bearing Ratio (CBR) on the soil/shredded building debris material for this project. CBR is a penetration test for evaluation of the material mechanical strength. The test is performed by measuring the pressure required to penetrate a soil sample with a plunger of standard area. The measured pressure (k) is then divided by the pressure required to achieve an equal penetration on a standard crushed rock material (assumed as 3400 psi). Physical and mechanical properties of three test samples were shown in Table 1.

Table 1: Physical and Mechanical Properties

Samples	Density	Water Content	k	CBR
S1	66.5psf	11.8%	44psi	1.3
S2	69.1psf	21.2%	84psi	2.5
S3	67.4psf	27.3%	73psi	2.1

Average CBR value 2 were selected for the following analysis. Based on the approximate relationship with CBR, bearing capacity could be assumed as 4 psi (575 psf).

$$Q = \frac{1}{2}B\,\gamma\,N_\gamma + D_f\gamma\,N_q$$

11301 Olive Lane Anchorage, Alaska 99515 Phone: 907-344-5934 Fax: 907-344-5993

With Q being 575 psf, N_γ and N_q are ø-dependent terms. Assuming D_f= 1 ft, B = 1 ft, and γ = 67 psf, it is calculated that ø is approximate 20°.

Provided proper engineering controls (sheeps foot compacted), this material will stand an approximately 2H:1V slope, with a vertical height less than 15 ft.

The strength of the mixture will be a function of the amount of mineral soil in the mixture, which is expected to be quite variable. Our samples used for testing have minimal mineral soil, thus representing a minimum slope value.

We appreciate the opportunity to provide you with our services. If you have any questions, please do not hesitate to contact us at your convenience.

Sincerely,

Northern Geotechnical Engineering, Inc. *d.b.a.* Terra Firma Testing,

Xiaoxuan (Eva) Ge, E.I.T.

Subject: **Shredded C & D Material with Soil Testing Procedure**

No water was added to the shredded C & D material with soil prior to densification testing.

An approximate 2' loose lift of shredded C&D material with soil was bladed over the testing vessel and statically densified by using the tracks of a bulldozer. Upon completion of the track densification the testing vessel was carefully excavated out of the compacted lift and the top struck flush. The testing vessel was then hoisted onto a digital platform scale to determine the unit weight.

If you have any questions or require additional information, please contact the undersigned.

Anchorage, AK 99501
Attn: Shane Durand

RE: CMS Proposed Monofill Site, Palmer Alaska

Subj: Analysis of On Site Soils for Use in Construction of the Monofill

This letter describes the results of the percolation tests and laboratory tests performed on typical soils at the project site. The in-situ percolation tests were performed on July 1, 2013, at the proposed Palmer Monofill site by Aaron Acena, a geologist from Environmental Management, Inc. (EMI) under the oversight of Larry Helgeson, P.E. The laboratory analysis was conducted by Terra Firm Testing of Anchorage.

The standard 6-inch falling head pressure test that is recommended by Alaska Department of Environmental Conservation (ADEC) was used to complete the tests. Boreholes were dug to a depth of approximately 2 feet in 3 areas on the property which appeared to represent "native" soil conditions on site that would be found under the monofill. Holes 1 and 2 were located within 50 ft. of each other on the south end of the property and a 3rd hole was dug closer to the west/central area of the property in a flattened zone. Holes were prepped with 2 inches of gravel at the base and allowed to soak for 1-2 hours before the test. Hole 3 exhibited water movement that qualified as ready to test "as is" without soaking. Holes 1 and 2 indicated additional soaking would be required before a percolation test could be used to meet ADEC requirements to test soils for a leech field. The final percolation rate will likely be slower than these tests indicate. The preliminary percolation rates were taken from an average of the last three readings taken from each hole and are listed in Table 1.

Table 1

Location ID	Percolation Rate (min/in)
Hole 1	41
Hole 2	81
Hole 3	7

206 E. FIREWEED LANE, SUITE 201 • ANCHORAGE, AK 99503-2703
CONSULTING (907) 272-9336 • FAX (907) 272-4159 • TRAINING (907) 272-8852 • FAX (907) 272-0319
www.emi-alaska.com

These percolation tests indicate most of the soil is very suitable for the base of a monofill, allowing any accumulated storm water to slowly percolate into the ground. In areas where the soils has long percolation rates, such as around Hole 2, the bottom of the cells will need to be graded to prevent ponding. In addition, storm water control, such as interception ditches, should be constructed to prevent additional storm water from entering the cell area.

The soils from the locations selected as possible source material for covers for the cells were sent to Terra Firma Testing in Anchorage for gradation testing and checking the hydraulic conductivity. The predominant materials available on site consist of silts and sands with some gravel. With a hydraulic conductivity of around 10^{-4} cm/sec these soils will be suitable for use on intermediate caps and the final cap for the cells.

Sincerely,
Environmental Management, Inc.

To: Shane Durand
Subject: Market research

As per your request I have looked at the value of homes sold around local waste disposal sites to determine if there is a risk of adjoining property values declining. I looked at homes in the Majestic Hills subdivision and since 2005 when homes were originally built home values have increased between 10 and 25% according to the report on closed listings. Homes in this subdivision do not appear to have a lesser value then homes in similar subdivisions located further from the Alaska Demolition Monofill. Similarly homes in the Chugiak area do not have a history of losing value based on the proximity to the land fill. I have had a home at the end of Skyview on the corner of Wildwood Drive since 1982 and have not seen the landfill effect home values in that area. I bought my home in 1982 for $110,000 and it is now worth $230,000 or more as an example of home values increase in that area.

In reviewing property disclosure forms another thing I found very interesting is that sellers adjacent to the Alaska Demolition Monofill in several cases did not acknowledge there is a site in these areas, Page 5 of the State of Alaska Property Disclosure, asks if you are aware of any waste disposal site or a gravel pit within one mile radius of the property. In some cases it was marked No, and others did not mark it an all. For sellers to not be aware of an adjacent gravel pit of Waste site would indicate that these are very unobtrusive operations that would not have adverse impact on property values.

Based on the review of sales data the overall value of the properties located around the Alaska Demolition Monofill, MSB Landfill and Former Chugiak Landfill have increased at the same rate as properties further away.

Based on this I would not expect your proposed facility to impact surrounding property values particularly not 10% or more.

This guidance document is intended to give building owners, inspectors, and contractors information on how to best handle the materials and wastes resulting from the construction, demolition, and renovation of buildings. Federal regulations require the removal of all asbestos-containing materials and all hazardous or toxic materials before demolition or renovation of a building begins. Contractors will provide a safer environment for their workers and the public by giving proper attention to the wastes generated by a project before demolition or renovation begins.

Topics Covered

- The First Step: The Building Survey
- What if a Building Has Asbestos?
- What about Hazardous Waste?
- What if I Want to Burn the Woody Debris?
- How Do I Dispose of Non-Hazardous Waste?
- What Wastes Can be Disposed Without an ADEC Solid Waste Permit?
- Contact Information

The First Step: The Building Survey

As mentioned above, the federal regulations require the removal of all asbestos-containing materials and hazardous or toxic materials prior to beginning a building demolition or renovation. Identifying the location and approximate amounts of these materials is most readily accomplished by completing a building survey. Once each waste type is identified and located, it can then be removed from the building according to appropriate state and federal regulations and best management practices and recycled or disposed in the most appropriate manner. A building survey does not need to be complicated and there are different methods for doing a survey. You should develop a method that best fits your needs.

Handling & Disposal of Construction & Demolition Waste

August 2011

Removal of asbestos and hazardous wastes **after** demolition is difficult and expensive. By knowing the types and quantities of all wastes that will be generated, you can plan ahead and figure out how to recycle or dispose of those wastes in the most efficient and safest manner. Even though it may be difficult to correctly identify all the material, a thorough investigation can save you many headaches later.

Once you have surveyed your project and know all the types and amounts of materials that will be generated, you can determine which materials can be recycled, burned, or disposed. The most common methods for disposing of different wastes will be discussed in this document. Please contact your local landfill, recycling facility, or sponsoring organization for recycling information. Some common recyclable wastes include piping, conduit, fixtures, timbers, windows, and doors.

Federal law requires that you contact EPA before demolition begins, regardless of the type of waste involved. Contact them after you have identified the types of wastes the project will generate.

What If a Building Has Asbestos?

Regulated Asbestos-Containing Material (RACM) must be removed prior to the demolition of a building and must be disposed at a landfill permitted to accept RACM wastes.

RACM waste is any asbestos-containing material that contains more than 1% asbestos, and that when dry, can be crumbled or reduced to powder by something as minor as hand pressure. If it can be crumbled or reduced to powder relatively easily, it is called "friable".

Non-RACM waste, on the other hand, is asbestos-containing material that is not friable or is not likely to become friable during the demolition or renovation activities. In other words, it is material that when dry cannot be crumbled, pulverized, or reduced to powder by hand pressure or by the demolition or renovation process. Non-RACM waste can be disposed at a permitted construction and demolition waste landfill or at a permitted municipal solid waste landfill provided the operator is willing to accept the waste.

For projects in rural areas without a nearby permitted landfill, the project may qualify for an authorization for the one-time disposal of asbestos waste. Such authorizations are described in greater detail in the section "How Do I Dispose of Demolition Waste?" ADEC Solid Waste Program staff can help you determine if this is an option for your project.

You will typically find asbestos-containing material in anything that was intended to retard fires. Specifically look at door gaskets, duct insulation, and the tape at duct connections of furnaces, boiler, and wood stoves. Hot water pipes inside walls and the tees, valves, elbow, and cross connections should also be checked. Wall board; mastic, acoustical tile or sprayed-on ceilings; roof felt and shingles; window putty; cement asbestos board siding and undersheeting; electrical equipment such as

lamp sockets, outlet and switch boxes, recessed lighting units, and old-fashioned wiring insulation, and older electrical appliances may be additional sources for asbestos-containing material.
It is important in older facilities such as HUD housing, FAA buildings, and military facilities to survey the flooring. Many floors had 1½ to 3 inches of material stacked on top of one another. Asbestos-containing material may be in some or all of the layers.

Asbestos waste may not be burned because it does not burn but just becomes airborne. Therefore, it is important to remove all asbestos-containing materials if your intention is to burn debris after a building is demolished. Note that if non-RACM waste catches fire, it becomes regulated by EPA under the National Emission Standards for Hazardous Air Pollutants (NESHAP) program.

Once you have identified and located any RACM waste, you must arrange for a certified contractor to remove it. The contractor will package and ship it to a landfill that is permitted for RACM waste. Contractors certified to remove RACM waste can be found in the telephone directory, usually under environmental/ecological services.

Remember to notify EPA before any asbestos removal or building demolition begins. The EPA requires notification ten working days in advance so they have an opportunity to inspect the job. They can provide greater detail as to what is or is not considered RACM waste. The regulations can be complex, and EPA welcomes the opportunity to provide clarification and assistance. You can contact EPA at the Alaska office at 907-271-3688 or 800-781-0983, or the Seattle office at 206-553-4226.

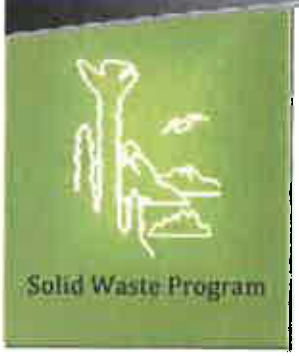
What about Hazardous Waste?

Federal regulations define what materials are considered hazardous waste and how these materials must be disposed. Contact EPA at 907-271-6329 or 800-781-0983 for more information.

Hazardous wastes commonly found in a demolition project include:

- Some lead painted materials;
- Some fluorescent tubes and spent incandescent bulbs;
- Lead pipe and solder
- Mercury switches;
- Lead based paint;
- Some liquid paint wastes;
- Unused solvent based paints;
- PCB containing transformers (classified as toxic);
- PCB containing light ballasts (classified as toxic).

Federal and State occupational safety and health regulations may apply if your project involves hazardous materials, such as asbestos- or lead-containing products, and your workers may need to be certified or specifically trained. Please contact Alaska Occupational Safety and Health for more information.



If you are demolishing a building which has an air conditioning system, you must recover the refrigerant, something that may only be done by a certified technician. Simply venting the refrigerant into the air is prohibited.

Burning hazardous wastes or any materials that may emit a toxic gas when burned is prohibited. This includes such things as certain chemicals, tars, linoleum, plastic, foam insulation, rubber, toxic waste, lead pipes, and PVC plastic piping.

When determining the amount of hazardous waste that will be generated, you must include all the hazardous products used for removing building materials.

State law generally prohibits the disposal of hazardous waste in the state. However, small quantity generators of hazardous waste (those that generate less than 220 pounds per month per site) can dispose of their hazardous wastes at a permitted Class I or II landfill. If you are registered with the EPA as a small quantity generator, contact your local landfill to find out if it is a Class I or II landfill with a current permit and is will to accept "conditionally exempt small quantity generator" waste.

If the local landfill does not have a Class I or II permit, you may be able to transport the waste to another Class I or II landfill for disposal, if that landfill accepts hazardous waste from outside its municipal boundary. Contact the landfill and/or ADEC Solid Waste Program for more information.

If your demolition project produces more than 220 pounds of hazardous waste in a month, you will need to ship this waste out of state to an EPA-registered treatment, storage, and disposal facility.

What if I Want to Burn the Woody Debris?

Controlled burning of clean, woody debris from construction, demolition, or land clearing projects is allowed in most areas of Alaska, but it needs to be conducted in a manner that doesn't create a nuisance or become a health hazard to local residents. "Clean woody debris" means wood that has not been treated with a paint containing cadmium or lead, or with a weatherizing preservative (such as pentachlorophenol or creosote).

It is important to note that burning is <u>not</u> considered to be complete disposal for construction and demolition waste because the ash and unburned debris must be disposed at a permitted landfill. You may also be required to test the ash and debris in order to verify that it is non-hazardous (see previous section for hazardous waste management).

Solid Waste Program

Ash from the burning of land clearing waste is not a solid waste and is therefore not required to go to a landfill. However, if you are burning greater than 40 acres of land clearing debris, or if black smoke will be produced, you will need a permit from ADEC's Air Quality Program. Some areas in Alaska require coordination with and permits from the local authorities. For instance, if your project is located in Fairbanks, Anchorage, Ketchikan, Homer, or Juneau, you need to contact local government authorities for approval. In some areas, the Alaska Department of Natural Resources, Division of Forestry may also require a burn permit. It is always wise to contact the local fire department to let them know you will be burning in the area.

To learn more about burning woody debris in your project area, please contact the ADEC Air Quality Program at: Interior 907-451-2114 or South Central and Southeast 907-269-6847. Or visit their website at http://www.dec.state.ak.us/air/ob.htm.

How Do I Dispose of Non-Hazardous Waste?

If the waste you generate is not an EPA-regulated hazardous waste and is not exempt from state permit requirements (see next section), you must dispose of it at a permitted solid waste landfill. This may be an existing facility or a landfill specifically permitted for your project. A solid waste permit ensures that waste is disposed at a suitable location and in a way that will minimize the likelihood of pollution or associated health problems. If you plan to take waste to a permitted facility, you should contact them directly. If you want to permit a project-specific landfill, contact the nearest ADEC Solid Waste Program office regarding whether you will need an inert waste landfill permit or an asbestos landfill permit. Program staff will discuss your situation with you and help you determine which option is best for the project. The permit application review and public notice process will begin after a completed application and the required fee is received.

Another option that may apply to your project is obtaining an authorization for a one-time disposal of either inert or asbestos waste. These authorizations come with strict limitations on the amount of waste allowed in the one-time disposal so not all projects will qualify for these. ADEC provides two types of one-time authorizations for remote construction and demolition projects:

- **Authorization for one-time disposal of asbestos-containing waste.** This authorization allows the disposal of up to 250 cubic yards of RACM and non-RACM waste that is generated on the project site. This authorization pertains only to projects in locations that do not have year-round road access to the national highway system and are more than 50 miles from a permitted landfill. If your situation does not fit these conditions, you will need to apply for an asbestos waste monofill permit. You should also contact EPA to determine if any federal regulations will apply to the project.

Handling & Disposal of Construction & Demolition Waste

August 2011

Solid Waste Program

- **Authorization for one-time disposal of inert waste.** This authorization allows the one-time disposal of up to 1,000 cubic yards of building debris and other inert wastes, but does not include asbestos waste or non-salvageable scrap metal debris. This authorization may only be used for disposal of wastes in locations that are 100 miles from the nearest permitted landfill that can be reasonably accessed or if all reasonably-accessed landfills within 100 miles refuse to accept the waste. If your situation does not fit these conditions, you will need to apply for an inert waste monofill permit.

What Wastes Can Be Disposed Without an ADEC Solid Waste Permit?

Most building construction and demolition debris is considered "low risk," which means that it has little or no potential to cause pollution problems. Some wastes such as concrete, brick, and mortar are considered "very low risk" and are usually not regulated. This "exempt" waste does not need to go to a permitted landfill, as long as it is not mixed with other wastes. Examples of exempt wastes that you might encounter during demolition, renovation, or construction projects include:

- Land clearing waste, including excavated dirt, rock soil, butt ends, limbs, stumps, or other foliage;
- Portland cement type concrete and associated steel rebar that can't be easily removed;
- Crushed glass except for television tubes, fluorescent light tubes, or computer monitors;
- Crushed asphalt pavement used in:
  - A building pad or parking area as road base or pavement; or
  - As a material to construct a containment berm for a tank farm

Contact the ADEC Solid Waste Program for more about different disposal options and exempt waste.

Asbestos

Asbestos is a generic term used to describe a group of fibrous silicate minerals that occur naturally in the environment and have been mined for commercial use. The asbestos minerals have high tensile strength, the ability to be woven, and resistance to heat and most chemicals. Because of these properties, asbestos fibers have been used in a wide range of heat resistant, durable manufactured goods.

Asbestos

The physical properties of asbestos are also the reason that asbestos is not expected to move through soil. It is a mineral (i.e., rock) and dense, having a specific gravity typically reported as ranging between 2.0 and 3.5 (two to three and half times heavier than water), depending on the mineral variety. Asbestos is made up of fibers that are not soluble and, therefore, **cannot be transported in a water solution**. The particles are also too large to be transported preferentially by other physical-chemical processes like diffusion. Therefore, asbestos fibers tend to remain stationary within the soil matrix. In other words, in a natural soil setting, **asbestos fibers do not move through the soil**. Based on studies of other insoluble particles of similar size, the expected migration rate of an asbestos fiber through soils by the forces of groundwater is approximately 1 to 10 centimeter (.4 to 4 inches) per 3,000 to 40,000 years. Thus, **asbestos is not considered a groundwater contaminant.** (Berkland, 1974)

PLANNING COMMISSION NOVEMBER 7, 2016

- **Concerns**
  - **Hazardous Waste**
    - **NO Hazardous Waste Accepted**
    - **Asbestos is not a Hazardous Waste**
    - **Inspections by EPA Certified inspectors**
    - **Video Surveillance**
    - **If something were to be dumped its reported to EPA and OSHA as a spill. The spill is cleaned up by properly certified workers and the customer charged. CRS has done this before.**

PLANNING COMMISSION NOVEMBER 7, 2016 Page 497

- Concerns
  - Water Quality
    - Follow DEC design
      - Monofill is not in the ponds
    - NO WASTE DUMPED IN PONDS
    - Monitoring wells
    - Asbestos does not leach or migrate through soil
    - Proper institutional designs and controls

PLANNING COMMISSION NOVEMBER 7, 2016 Page 498

- **Concerns**
  - **Air Quality**
    - **Debris covered per ADEC requirements**
    - **The berms around each cell help contain material**
    - **Fences if needed**
    - **Water for dust control**

PLANNING COMMISSION NOVEMBER 7, 2016 Page 499

- **Concerns**
  - **Noise Pollution**
    - **White noise passive back up alarms**
    - **Day time monofill operations**
    - **Less Noise than Gravel Pit**
    - **Meets MSB Code**
    - **Size and topography of site will limit noise**

PLANNING COMMISSION NOVEMBER 7, 2016 Page 500

- Concerns
  - Why this site
    - Existing Monofills are not controlled as tightly
      - MatSu Borough open to public and no inspection
    - Comparative limited residential surrounding the site
    - Surrounded on 3 sides by industrial gravel operations and a shooting range
    - Traffic in and out on Glenn Highway not through neighborhoods
    - Central location to collect recyclables in the Valley
    - Existing site topography favorable for site screening

PLANNING COMMISSION NOVEMBER 7, 2016 Page 501

- Concerns
  - Property Values
    - State property disclosure requires notice if within one mile of Gravel Pit or Waste Site
    - Data does not support claim that property values decrease near waste sites. Look at properties adjoining other Sites.
      - Matanuska Borough Landfill
        - East Lee Ann Drive 3% increase
        - East Loma Rica Drive 1% increase
        - East Strand Drive 5% increase
      - Alaska Demolition Monofill
        - South Pinnacle Drive No Change
        - South Idaho Peak 1% increase
    - Properties have been increasing in value
    - After closure and reclamation it may increase value due to the recreational opportunity

PLANNING COMMISSION NOVEMBER 7, 2016 Page 502

- Concerns
  - Closure and Reclamation
    - DEC permit requires substantial financial bond to cover closure
    - Central Companies have significant insurance including pollution liability

PLANNING COMMISSION NOVEMBER 7, 2016 Page 503

1. Introduction

TERRASAT Inc. (TERRASAT) was retained by Environmental Management, Inc. (EMI) to develop a ground water monitoring plan at Central Monofill Services (CMS) site of a proposed monofill in Palmer, Alaska. (see Figure 1).

TERRASAT followed the Clean Water Act 40 CFR 258.54 "Detection Monitoring Program" in developing the *Detection Monitoring Plan* and used guidelines established in ASTM D 6312-98 "Standard Guide for Developing Appropriate Statistical Approaches for Ground-Water Detection Monitoring Programs" in creating the *Detection Monitoring Plan* for this project.

The State of Alaska, Department of Environmental Conservation (ADEC), Solid Waste Management Program recognizes the ASTM D 6312-98 procedure as a valid approach when applied to landfills and solid waste disposal sites. See Appendix A for a discussion of this procedure and Appendix B for example calculations.

According to the 18 AAC 60.820, groundwater monitoring and corrective action is required for all solid waste disposal facilities with eight exceptions. The CMS Palmer monofill is granted exception to groundwater monitoring and corrective action under 18 AAC 60.820 number 8, which grants exception to "a Class II MSWLF inert waste monofill located in an area that receives 25 inches or less in total precipitation each year". The CMS Palmer monofill will contain inert waste and is located in an area with less than 25 inches of total precipitation each year. According to www.usclimatedata.com, Palmer, Alaska receives 15.8 inches of precipitation each year.

Environmental stewardship is important to CMS. Though not required by regulations, as a good faith effort and in response to concerns, CMS will monitor groundwater on their site to detect potential unanticipated impacts to the groundwater in time to take corrective action to ensure a release does not occur.

This plan includes the use of two down-gradient monitoring wells and one up gradient well (see Figure 2) to obtain a statistically representative model.

The groundwater monitoring plans includes initial baseline sampling followed with detection monitoring after two quarterly baseline sampling events. Detection monitoring is defined in ASTM D 6312-98 as *"ground water monitoring that is intended to detect a potential impact from a facility by testing for statistically significant changes in geochemistry in a down gradient monitoring well relative to background levels"*. After baseline sampling is complete, a hierarchical analysis will be conducted and prediction limits will be calculated for one or two analytes that would be indicators used to predict a potential for a release. Subsequent detection monitoring will continue to monitor these indicator analytes to identify the potential for a release and the possible source.

2. Monitoring Wells

2.1. Locations

Figure 2 shows the location of the two proposed down-gradient wells and the one proposed up-gradient well. The well locations were chosen to provide the best locations for the detection of a release (the down-gradient wells) and to monitor up gradient background groundwater characteristics. Figure 2 shows the monitoring wells in the project area.

2.2. Installation Procedures

Well installation followed the guidelines established in the ADEC – SPAR document Monitoring Well Guidance, updated November 2011. This document fulfills the regulatory requirements of 18 AAC 75 and 18 AAC 78 for monitoring well design, construction, installation, maintenance, and decommissioning. Monitoring wells were constructed at least four feet below the top of the water table with 10 foot screens bedded in sand. The wells will be constructed at least four feet below the top of the water table. Bentonite chips or grout was used to seal the well/aquifer from meteoric water/potential surface contaminates traveling along the casing. Figure 3 illustrates the typical well installation procedures used for this project.

3. Water Quality Monitoring

3.1. Aquifer Productivity and Quality

The CMS Palmer Monofill will use a 35 acre area with a design capacity of 2.2 million cubic yards for inert construction debris. This debris will be screened to remove recyclable and hazardous materials. Both regulated and non-regulated asbestos containing materials (NON-RACM) will be disposed in the monofill. The ACM will be placed in a designated cell and covered daily. When the cell is complete, its limits will be surveyed and recorded. TERRASAT investigated bore hole logs of eight previously drilled bore holes on the property, logged by Shannon and Wilson, Inc. (see Figure 5 for a list of bore hole logs). The eight wells were constructed in the unconfined aquifer with water levels varying from 3 to 35 feet below ground surface (BGS). Generally, the water table is encountered closest to the surface near the man made ponds on the site and deepens toward the southwest. Wells N-15 and N-20, which are the most down-gradient wells on the property in the past, did not encounter groundwater. N-20 was drilled 41 feet and N-15 was drilled 120 feet. TERRASAT'S opinion is monofill operations as designed, with at least 10 feet of undisturbed soil separation above the water table will have no impact on productivity of the unconfined aquifer.

3.2. Baseline Monitoring

This monitoring plan proposes to sample a baseline suite of analytes at the three designated monitoring wells. Baseline monitoring will consist of selected analytes listed in "Table J – Optional Monitoring Constituents and Parameters" of the 18 AAC 60. After three years of baseline sampling, CMS will potentially reduce the suite of analytes for a detection monitoring plan by following ADEC accepted procedures. Figure 4 lists the baseline suite of analytes.

3.3. Detection Monitoring

The results of principal component analyses of baseline data will lead to a determination that some constituents best represent the characteristics of the water table aquifer. From these principal components, a list of constituents will be chosen as *potential* indicators, based on their score within a statistical principal component matrix.

After potential indicator constituents are selected using principal component analysis of baseline data, a further reduced list of indicator constituents will be selected that are statistically valid to provide early warning, should a release occur during monofill operations. For each constituent chosen to be included in the final indicator list, a prediction limit will be calculated based on available sampling results. Monitoring will include pH and conductivity as well as those constituents determined by baseline sampling to be valid indicator analytes for this project.

This plan is designed as an early detection program for potential releases. The plan's creation and implementation is based on the following actions:

- ◊ Creating a database of baseline sampling results
- ◊ Evaluating subsurface conditions at study area
- ◊ Determining the statistical distribution of sample results
- ◊ Selecting appropriate indicator constituents to be monitored for the detection of a release
- ◊ Determining prediction limits of indicator constituents
- ◊ Re-evaluating prediction limits when new sampling data are available
- ◊ Evaluating sampling data after each sampling event to determine if a release occurred
- ◊ Conducting verification re-sampling if a release is suspected
- ◊ Implementing a release investigation if verification sampling suggest a release
- ◊ Initiating corrective action and monitoring if a release is detected

3.4. Sampling Frequency

Constituent sampling will be conducted on a bi-annual basis, spring and fall, to assure that variability of ground water is being evaluated (see Appendix C Table 1). Groundwater level measurements will be collected and recorded for the three designated monitoring wells. Initially water level measurements will be collected approximately bi-monthly from monitoring wells until October. After that time, water level will be monitored approximately monthly. Less frequent water level monitoring will be conducted after one year. See Appendix C Table 2 for water level measurement monitoring schedule. CMS will report the sampling annually to the applicable regulatory agency and if a release is confirmed.

3.5. Duration of Monitoring

Unless evidence of a release occurs, water quality monitoring will cease one year after the monofill is no longer in use. If a release occurs, then water quality monitoring may be required as part of a long-term remediation plan.

4. Release Actions

If analyte concentrations exceed the prediction limits, verification re-sampling will be conducted in the wells that exceed the prediction limit. If verification re-sampling confirms a release, a release investigation will be initiated. The release investigation may use the baseline-full suite of constituents for comparison with existing background data. A report of the release investigation will be submitted to the appropriate government agencies within 60 days of receipt of the final laboratory reports. If baseline data shows a analyte is above the drinking water standard naturally, it will be statistically evaluated using Shewart-CUSUM control charts that indicate anthropogenic input based on the analytes seasonal trends.

Please contact us at (907) 344-9370 if you have any questions or would like further information.

Many landfills in the state of Alaska are required to conduct groundwater monitoring to ensure that the landfill is not affecting groundwater quality. There are actually two types of groundwater monitoring and this fact sheet explains the difference between the two types.

Detection Monitoring
Most landfills are doing what is called detection monitoring, which is intended to "detect" if the landfill is impacting groundwater quality.

An important aspect of detection monitoring is that the analytical results of the monitoring are not compared to water quality standards. This is because the purpose of the monitoring is strictly to determine if there is an impact, which is defined as a statistically significant change in the concentration of one or more parameters.

Concentrations of substances in ground water tend to fluctuate. One or two measurements that exceed background levels don't necessarily mean the landfill is impacting the groundwater. Analysts must look at all the data to determine if there has been a 'statistically significant' increase in pollution.

So, rather than comparing to water quality standards, the analytical results are compared to background concentrations: the concentrations that would normally be found in groundwater in that area. If detection monitoring documents a statistically significant increase above background concentrations that is caused by the landfill, then the landfill operator must begin assessment monitoring.

Assessment Monitoring
The purpose of assessment monitoring is to assess the extent and nature of the impacted groundwater. This includes determining what pollutants are impacting groundwater, whether those pollutants exceed applicable standards, and how far the pollution extends. For a more detailed description of assessment monitoring, see the *"Assessment Monitoring Requirements"* fact sheet.

Compared to detection monitoring, assessment monitoring includes a longer list of required analyses, more frequent monitoring, and the monitoring results are compared to an applicable water quality standard. For more information on these standards, see the *"Water Quality Standards for Groundwater Monitoring"* fact sheet.

If assessment monitoring shows that any contaminants exceed water quality standards, then the facility must take corrective action to clean up the pollution and ensure that the problem doesn't continue. If monitoring shows that all contamination is below water quality standards, the facility must continue assessment monitoring to ensure that levels do not rise above the standards. The assessment monitoring program ends only when groundwater quality has been restored to the natural background conditions.

Appendix B

Example Calculations of Prediction Limits for Detection Monitoring

Prediction Limit for Next Measurement

$\mu := 3.29$ Mean

$\sigma := 1.72$ Standard deviation

$k := 18$ k is the number of comparisons (sampling stations times constituents)

$n := 18$ Number of background measurements

$df := n - 1$ Degrees of freedom

$t_{.95} := qt(.95, df)$ Student's T for 95%

$$PL := \mu + t_{.95} \cdot \sigma \cdot \sqrt{1 + \frac{1}{n}}$$

$PL = 6.364$ Upper prediction limit for the next single measurement from a normal distribution. Use this for detection.

Prediction Limit for Verification Resample

$$PL_{1\_of\_1} := \mu + t_{1\_of\_1} \cdot \sigma \cdot \sqrt{1 + \frac{1}{n}} \qquad PL_{1\_of\_2} := \mu + t_{1\_of\_2} \cdot \sigma \cdot \sqrt{1 + \frac{1}{n}}$$

$$PL_{2\_of\_2} := \mu + t_{2\_of\_2} \cdot \sigma \cdot \sqrt{1 + \frac{1}{n}}$$

$PL_{1\_of\_1} = 6.3$ Upper prediction limit for one of one verification resamples

$PL_{1\_of\_2} = 5.247$ Upper prediction limit for the first verification resample or one of two verification resamples

$PL_{2\_of\_2} = 6.636$ Upper prediction limit for the first one or two of two verification resamples

1. Introduction

TERRASAT Inc. (TERRASAT) was retained by Environmental Management, Inc. (EMI) to develop a ground water monitoring plan at Central Monofill Services (CMS) site of a proposed monofill in Palmer, Alaska. (see Figure 1).

TERRASAT followed the Clean Water Act 40 CFR 258.54 "Detection Monitoring Program" in developing the *Detection Monitoring Plan* and used guidelines established in ASTM D 6312-98 "Standard Guide for Developing Appropriate Statistical Approaches for Ground-Water Detection Monitoring Programs" in creating the *Detection Monitoring Plan* for this project.

The State of Alaska, Department of Environmental Conservation (ADEC), Solid Waste Management Program recognizes the ASTM D 6312-98 procedure as a valid approach when applied to landfills and solid waste disposal sites. See Appendix A for a discussion of this procedure and Appendix B for example calculations.

According to the 18 AAC 60.820, groundwater monitoring and corrective action is required for all solid waste disposal facilities with eight exceptions. The CMS Palmer monofill is granted exception to groundwater monitoring and corrective action under 18 AAC 60.820 number 8, which grants exception to "a Class II MSWLF inert waste monofill located in an area that receives 25 inches or less in total precipitation each year". The CMS Palmer monofill will contain inert waste and is located in an area with less than 25 inches of total precipitation each year. According to www.usclimatedata.com, Palmer, Alaska receives 15.8 inches of precipitation each year.

Environmental stewardship is important to CMS. Though not required by regulations, as a good faith effort and in response to concerns, CMS will monitor groundwater on their site to detect potential unanticipated impacts to the groundwater in time to take corrective action to ensure a release does not occur.

This plan includes the use of two down-gradient monitoring wells and one up gradient well (see Figure 2) to obtain a statistically representative model.

The groundwater monitoring plans includes initial baseline sampling followed with detection monitoring after two quarterly baseline sampling events. Detection monitoring is defined in ASTM D 6312-98 as *"ground water monitoring that is intended to detect a potential impact from a facility by testing for statistically significant changes in geochemistry in a down gradient monitoring well relative to background levels"*. After baseline sampling is complete, a hierarchical analysis will be conducted and prediction limits will be calculated for one or two analytes that would be indicators used to predict a potential for a release. Subsequent detection monitoring will continue to monitor these indicator analytes to identify the potential for a release and the possible source.

2. Monitoring Wells

2.1. Locations

Figure 2 shows the location of the two proposed down-gradient wells and the one proposed up-gradient well. The well locations were chosen to provide the best locations for the detection of a release (the down-gradient wells) and to monitor up gradient background groundwater characteristics. Figure 2 shows the monitoring wells in the project area.

2.2. Installation Procedures

Well installation followed the guidelines established in the ADEC – SPAR document Monitoring Well Guidance, updated November 2011. This document fulfills the regulatory requirements of 18 AAC 75 and 18 AAC 78 for monitoring well design, construction, installation, maintenance, and decommissioning. Monitoring wells were constructed at least four feet below the top of the water table with 10 foot screens bedded in sand. The wells will be constructed at least four feet below the top of the water table. Bentonite chips or grout was used to seal the well/aquifer from meteoric water/potential surface contaminates traveling along the casing. Figure 3 illustrates the typical well installation procedures used for this project.

3. Water Quality Monitoring

3.1. Aquifer Productivity and Quality

The CMS Palmer Monofill will use a 35 acre area with a design capacity of 2.2 million cubic yards for inert construction debris. This debris will be screened to remove recyclable and hazardous materials. Both regulated and non-regulated asbestos containing materials (NON-RACM) will be disposed in the monofill. The ACM will be placed in a designated cell and covered daily. When the cell is complete, its limits will be surveyed and recorded. TERRASAT investigated bore hole logs of eight previously drilled bore holes on the property, logged by Shannon and Wilson, Inc. (see Figure 5 for a list of bore hole logs). The eight wells were constructed in the unconfined aquifer with water levels varying from 3 to 35 feet below ground surface (BGS). Generally, the water table is encountered closest to the surface near the man made ponds on the site and deepens toward the southwest. Wells N-15 and N-20, which are the most down-gradient wells on the property in the past, did not encounter groundwater. N-20 was drilled 41 feet and N-15 was drilled 120 feet. TERRASAT'S opinion is monofill operations as designed, with at least 10 feet of undisturbed soil separation above the water table will have no impact on productivity of the unconfined aquifer.

3.2. Baseline Monitoring

This monitoring plan proposes to sample a baseline suite of analytes at the three designated monitoring wells. Baseline monitoring will consist of selected analytes listed in "Table J – Optional Monitoring Constituents and Parameters" of the 18 AAC 60. After three years of baseline sampling, CMS will potentially reduce the suite of analytes for a detection monitoring plan by following ADEC accepted procedures. Figure 4 lists the baseline suite of analytes.

3.3. Detection Monitoring

The results of principal component analyses of baseline data will lead to a determination that some constituents best represent the characteristics of the water table aquifer. From these principal components, a list of constituents will be chosen as *potential* indicators, based on their score within a statistical principal component matrix.

After potential indicator constituents are selected using principal component analysis of baseline data, a further reduced list of indicator constituents will be selected that are statistically valid to provide early warning, should a release occur during monofill operations. For each constituent chosen to be included in the final indicator list, a prediction limit will be calculated based on available sampling results. Monitoring will include pH and conductivity as well as those constituents determined by baseline sampling to be valid indicator analytes for this project.

This plan is designed as an early detection program for potential releases. The plan's creation and implementation is based on the following actions:

- ◊ Creating a database of baseline sampling results
- ◊ Evaluating subsurface conditions at study area
- ◊ Determining the statistical distribution of sample results
- ◊ Selecting appropriate indicator constituents to be monitored for the detection of a release
- ◊ Determining prediction limits of indicator constituents
- ◊ Re-evaluating prediction limits when new sampling data are available
- ◊ Evaluating sampling data after each sampling event to determine if a release occurred
- ◊ Conducting verification re-sampling if a release is suspected
- ◊ Implementing a release investigation if verification sampling suggest a release
- ◊ Initiating corrective action and monitoring if a release is detected

3.4. Sampling Frequency

Constituent sampling will be conducted on a bi-annual basis, spring and fall, to assure that variability of ground water is being evaluated (see Appendix C Table 1). Groundwater level measurements will be collected and recorded for the three designated monitoring wells. Initially water level measurements will be collected approximately weekly from monitoring wells until October. After that time, water level will be monitored monthly. Less frequent water level monitoring will be conducted after one year. See Appendix C Table 2 for water level measurement monitoring schedule. CMS will report the sampling annually to the applicable regulatory agency and if a release is confirmed.

3.5. Duration of Monitoring

Unless evidence of a release occurs, water quality monitoring will cease one year after the monofill is no longer in use. If a release occurs, then water quality monitoring may be required as part of a long-term remediation plan.

4. Release Actions

If analyte concentrations exceed the prediction limits, verification re-sampling will be conducted in the wells that exceed the prediction limit. If verification re-sampling confirms a release, a release investigation will be initiated. The release investigation may use the baseline-full suite of constituents for comparison with existing background data. The appropriate agencies will be contacted if the results are above the background prediction limit or the drinking water standard. If baseline data shows a analyte is above the drinking water standard naturally, it will be statistically evaluated using Shewart-CUSUM control charts that indicate anthropogenic input based on the analytes seasonal trends.

Detection vs. Assessment Monitoring At Municipal Landfills

April 2009

Many landfills in the state of Alaska are required to conduct groundwater monitoring to ensure that the landfill is not affecting groundwater quality. There are actually two types of groundwater monitoring and this fact sheet explains the difference between the two types.

Detection Monitoring
Most landfills are doing what is called detection monitoring, which is intended to "detect" if the landfill is impacting groundwater quality.

Concentrations of substances in ground water tend to fluctuate. One or two measurements that exceed background levels don't necessarily mean the landfill is impacting the groundwater. Analysts must look at all the data to determine if there has been a 'statistically significant' increase in pollution.

An important aspect of detection monitoring is that the analytical results of the monitoring are not compared to water quality standards. This is because the purpose of the monitoring is strictly to determine if there is an impact, which is defined as a statistically significant change in the concentration of one or more parameters.

So, rather than comparing to water quality standards, the analytical results are compared to background concentrations: the concentrations that would normally be found in groundwater in that area. If detection monitoring documents a statistically significant increase above background concentrations that is caused by the landfill, then the landfill operator must begin assessment monitoring.

Assessment Monitoring
The purpose of assessment monitoring is to assess the extent and nature of the impacted groundwater. This includes determining what pollutants are impacting groundwater, whether those pollutants exceed applicable standards, and how far the pollution extends. For a more detailed description of assessment monitoring, see the *"Assessment Monitoring Requirements"* fact sheet.

Compared to detection monitoring, assessment monitoring includes a longer list of required analyses, more frequent monitoring, and the monitoring results are compared to an applicable water quality standard. For more information on these standards, see the *"Water Quality Standards for Groundwater Monitoring"* fact sheet.

If assessment monitoring shows that any contaminants exceed water quality standards, then the facility must take corrective action to clean up the pollution and ensure that the problem doesn't continue. If monitoring shows that all contamination is below water quality standards, the facility must continue assessment monitoring to ensure that levels do not rise above the standards. The assessment monitoring program ends only when groundwater quality has been restored to the natural background conditions.

Appendix B

Example Calculations of Prediction Limits for Detection Monitoring

Prediction Limit for Next Measurement

$\mu := 3.29$ Mean

$\sigma := 1.72$ Standard deviation

$k := 18$ k is the number of comparisons (sampling stations times constituents)

$n := 18$ Number of background measurements

$df := n - 1$ Degrees of freedom

$t_{.95} := qt(.95, df)$ Student's T for 95%

$$PL := \mu + t_{.95} \cdot \sigma \cdot \sqrt{1 + \frac{1}{n}}$$

$PL = 6.364$ Upper prediction limit for the next single measurement from a normal distribution. Use this for detection.

Prediction Limit for Verification Resample

$$PL_{1\_of\_1} := \mu + t_{1\_of\_1} \cdot \sigma \cdot \sqrt{1 + \frac{1}{n}} \qquad PL_{1\_of\_2} := \mu + t_{1\_of\_2} \cdot \sigma \cdot \sqrt{1 + \frac{1}{n}}$$

$$PL_{2\_of\_2} := \mu + t_{2\_of\_2} \cdot \sigma \cdot \sqrt{1 + \frac{1}{n}}$$

$PL_{1\_of\_1} = 6.3$ Upper prediction limit for one of one verification resamples

$PL_{1\_of\_2} = 5.247$ Upper prediction limit for the first verification resample or one of two verification resamples

$PL_{2\_of\_2} = 6.636$ Upper prediction limit for the first one or two of two verification resamples

TERRASAT, Inc.
(907) 344-9370

Ground Water Solutions

Page 1 of 2

α is the false positive rate

t is the one-sided (1-α)*100% point on the Student's T distribution with n-1 degrees of freedom

$$\alpha_{1\_of\_1} := \left(1 - .95^{\frac{1}{k}}\right)^{\frac{1}{2}} \qquad t_{1\_of\_1} := qt\left(1 - \alpha_{1\_of\_1}, df\right)$$

$$\alpha_{1\_of\_2} := \left(1 - .95^{\frac{1}{k}}\right)^{\frac{1}{3}} \qquad t_{1\_of\_2} := qt\left(1 - \alpha_{1\_of\_2}, df\right)$$

$$\alpha_{2\_of\_2} := \sqrt{1 - .95^{\frac{1}{k}}} \cdot \sqrt{\frac{1}{2}} \qquad t_{2\_of\_2} := qt\left(1 - \alpha_{2\_of\_2}, df\right)$$

Appendix C

CMS Palmer Monofill Groundwater Monitoring Shedule

Appendix C: CMS Palmer Monofill Ground Water Monitoring Schedule

Table 1: Schedule of Constituent Monitoring for CMS Palmer Monofill

Year	Month	Constituent List	Wells
2013 - 2014	**May or June 2013	Baseline	ALL three monitoring wells
Duration of Project*	April	Detection-Indicator	ALL three monitoring wells
	October	Detection-Indicator	ALL three monitoring wells

*Constituents will be monitored as indicated for the duration of the project and for three years after the project terminates
** The two rounds of baseline samples have been taken at the time of this monitoring plan

Table 2: Schedule of Water Level Monitoring for CMS Palmer Monofill

Year	Dates of Monitoring	Water Level Measuring Frequency	Wells
2013-2014	April until October	Bi-Monthly, Approximately	ALL three monitoring wells
	October until April	Monthly	ALL three monitoring wells
Duration of Project*	Duration of project after April 2014	As deemed appropriate	ALL three monitoring wells

* Water level will be monitored as indicated for one year

Reference: **Conditional Use Permit Application – Request for Additional Information #1** Location: 17N02E18C010 & 17N02E19B006

Dear Ms. Lee:

In response to your request of February 13, 2014, Central Monofill Services, (CMS), submits the information below and attached, to provide clarifications and answer your questions in regards to our Conditional Use Permit Application. CMS has had additional modeling and testing performed by multiple experts in the field since the January submission of our application. This additional information is summarized below and attached. Amended pages to our original application are attached and addressed below. We would appreciate a quick processing of this application and should you have further questions please feel free to call or email them to accelerate the process. The additional information and clarifications provided for further support the finding that our CUP application meets the requirements of 17.60 and a CUP should be granted.

Questions and comments by the Matanuska Susitna Borough, (MSB), consultant J.A. Munter Consulting, Inc. (Munter), appears to raise a concern to Munter's, full understanding of the industry and regulatory structure. The waste industry is one of the most heavily regulated in the country. On a federal level the Environmental Protection Agency (EPA) and Occupational Safety Health Administration (OSHA) regulate nearly all aspects of the demolition, removal, processing and disposal of wastes. At the state level the Alaska Department of Environmental Conservation (ADEC) further regulates the identification and disposal of wastes throughout the state of Alaska. These regulations have been formed through years of federal and state research. The ADEC has established standards that can be used throughout Alaska regardless of local geology or climate. Most local authorities in Alaska lack the resources necessary to establish their own independent monofill or landfill regulations and even if they did the operator would still have to obtain the ADEC permits. As an example of operations under the current system, the MSB Central Landfill is designed to the ADEC standards and has both a lined Municipal Solid Waste (MSW) landfill and unlined C&D monofill

safely operating. MSB has not needed to issue specific regulations or operating conditions to protect the safety and health of the community.

The CMS monofill design and CUP application depends on meeting the ADEC standards to protect the health and safety of the public. During the June 3rd, 2013 Planning Commission hearing, MSB Assistant Borough Attorney, Lisa Richard made the following legal opinion to the planning commission "Taking all those things into consideration you must make a finding that the conditional use permit will not be harmful to the public health, safety, convenience and welfare the DEC is not required to make that finding before they can grant their permit." This opinion appears to directly contradict the ADEC Solid Waste Program regulations and standards that were developed specifically to, as stated in the ADEC mission statement, "Conserving, improving and protecting Alaska's natural resources and environment to enhance the health, safety, economic and social well-being of Alaskans." More specifically the mission statement for the ADEC, Solid Waste Program: "We are committed to protecting public Health and the environment through ensuring effective solid waste management, which includes landfills, treatment systems, and solid waste storage facilities."

The applicant should not have to prove the science used to develop state and federal regulations. Our facility has been designed to meet the standards established by the ADEC, a department charged with protecting public health. An Alaskan Professional Engineer designed the facility to these standards and placed his Professional Registration stamp on the design. Attached to the original CUP application and further addressed and attached are models and calculations showing the proposed facility can be operated without being harmful to the public health and safety. Due to the technical nature of these models and calculations, CMS requests a meeting with MSB staff and our professionals in which we can cover this information and answer any further questions staff may have.

The letter of February 13 is formatted as 26 numbered bullet points. Our response is in the order of the points followed with supplemental information:

1. *"The Borough hired J.A Munter Consulting, Inc. to review the application material. A copy of Munter's report, dated February 7, 2014, is attached for your review and comments. In addition to specific issues outlined below, address all issues raised in the Munter report."*

   Please see the attached response to the Munter report by Environmental Management Inc., Maddox and Associates, TERRASAT, Inc. and AlaskChem Engineering. In general, the Munter report is an opinion and provides no empirical evidence in objection to the Monofill portion of our submission. Attachments (1,2,3,4)

   Munter's review of the Initial Maddox report fails to take into consideration the criteria and procedures established in the CUP application. It does not appear Munter reviewed or understood the CUP application or ADEC standards. Munter takes very broad generalizations to the function of the monofill,

most of which contradict both the modeling performed for this facility and actual real world data from existing facilities throughout Alaska and elsewhere. Examples provided by Maddox for the Seward Landfill and Merrill Field Landfills, as well as AlaskChem's findings on MSB Landfills support the CMS design as being able to protect the health and safety of the public.

Munter's main contention is the large quantities of contaminated leachate he alleges will develop from the monofill and flow off site. Munters contention is disproved by the facts, modeling and calculations performed by the subject matter experts, and shown in the attached documents. With the combination of limited annual precipitation, seasonally frozen ground, evapotranspiration effects, run-off of precipitation and numerous other factors discussed in the attached monofill analysis there is very little transmission of water through the monofill, thus not creating the quantities of leachate Munter suggests. As shown in the attached documents, if minor amounts of leachate were generated it is not expected to contain harmful concentrations of contaminants.

Risks associated with earthquakes and neighboring gravel extraction in the groundwater table were evaluated and found not to have an impact on the monofill. These events may lead to short term changes in the water table but nothing that would reach the waste or saturate any waste in the monofill. Even modeling the upper limit of risks the monofill does not create a public health or safety hazard. The attached professional reports describe this in much more detail.

Leachate is produced by water contacting a soluble material for a sufficient duration causing the soluble to go into solution in the water, or an organic material decaying into leachate. The CMS facility will take primarily post recycling building debris. The 3" and smaller material is screened into a recycled product leaving a 3" to 12" typical size residual waste to be buried in the monofill. A 3" to 12" piece of building debris is not very soluble. Imagine a book size piece of carpet. Carpet in your home and carpet buried in a monofill do not dissolve into the limited water and decay extremely slowly. Carpet is inert, it does not turn to leachate. An example of a material decaying into leachate is fruit and vegetable matter that has high water content and rapidly decays. Fruit and vegetable matter is not inert and has to go to a municipal waste landfill, whereas the inert carpet and other building debris can go into a monofill.

Comparisons Munter draws between the proposed CMS facility and other prior landfill studies conducted in the lower 48 do not take into account several important factors. The type of waste in most of the facilities studied was unknown. Some landfills studied were actually Municipal Solid Waste (MSW) landfills or started as unlined MSW landfill before becoming inert debris fills. Many of the landfills studied were legacy landfills going back to a time before recycling and when very little inspection or control of the waste took place. This is a stark contrast to the facility proposed where all inbound materials are inspected and processed before disposal. Many materials that have caused concern for leachate production in the past are removed from the waste in the proposed facility. Examples include metals and sheetrock. Munters concerns over sulfate caused by gypsum/sheetrock do not take into consideration the large quantities of sheet rock removed from the waste and recycled by

CRS. Some former studies have shown elevated levels of heavy metals but again in this proposed facility metal is removed as it has a recycled commodity value.

On page 6 of the Munter review he states

The proposed CMS facility meets the ADEC required 500' separation distance to surrounding wells. Munter agrees in the concept of ADEC established drinking water well separation distances. These 100' minimum well and septic separation distances are established by the ADEC to protect the health and safety of the public, the same as the 500' separation distances ADEC has established between monofills and drinking water wells. These ADEC separation distances (500' between an inert waste monofill and water well) are all designed in and accounted for in the CMS proposed facility. Further, the professionally performed models of the CMS facility that are attached confirm that the separation distances established by ADEC are more than sufficient to protect the health and safety of the public.

2. "The application material states *"There are three industrial ponds located on the northern half of the property which cover 66 of the acres". "Of the remaining 52 acres, the monofill footprint is proposed to be 35.5 acres with 16.5 acres used for recycling operations". "The CUP is needed for 52 acres of the property"*. The site plan does not depict the conditionally permitted area. The proposed permitted area is irregular and does not correspond to lot lines. A surveyed delineation of the 52 acre boundary must be shown on the site plan. MSB 17.60.040(B) *Site Plan* requires *"the specific location of the use or uses to be made of the development shall be submitted with the application"*

See page A-2 Site Plan Drawing which shows a hatched area labeled as the "Material Storage and Recycling Areas" the Monofill area is circled with a heavy line. These are the "specific locations" of the uses submitted that make up the 52 acre specific location of the conditionally permitted area. For clarity see Attachment 5, which has this entire 52 acre area shaded and labeled as the "conditionally permitted area". Please replace page A-2 of our CUP package with Attachment 5 revised drawing. The proposed permitted area is irregular and does not correspond to lot lines in order to meet appropriate set back requirements. CMS did not see a requirement for the area to be regular in shape or along lot lines.

CMS is unclear of the MSB statement A "surveyed delineation" must be shown. 17.60.040(B) does not say a "surveyed delineation". The Site Plan shows the required "specific locations" and these could be surveyed onto the site for construction. The Site Plan shows the area bounded by property lines on the

west, south and east sides. The north side is bounded by off sets from the ponds or off sets from the closest section lines.

3. "Do you have a drainage plan for this site? If so, provide a copy. For example, what direction will material flow off the monofill? What direction will surface water be draining during construction of the monofill? MSB code section 17.60.040(B) Site Plan, states that "drainage" must be shown on the site plan."

See the original CUP package, Page A-4 Site Plan drawing. Note 7 states "Surface water drains perpendicular to the contour lines shown." The contour lines are shown on this drawing as well as the drainage basin, meeting the requirement to show drainage. Also see Page A-8 Cross sections, note 4 and the drawing for additional drainage shown. All drainage remains on site. In order to help clarify the site drainage, we have included Attachment 6, Sheet 8 Drainage Plan which has flow arrows shown.

4. "Is there a SWPPP (Storm Water Pollution Prevention Plan) for this site? If not, explain why one is not required?"

A SWPPP is not required for this site. A "No Exposure Certification" for exclusion from the NPDES industrial storm water permitting requirements is in place for this site. Please see the attached certificate from ADEC, Attachment 8.

5. "Please address the State of Alaska, Department of Transportation's plans for widening the Glenn Highway and placing an intersection at Colleen Street and how that might affect this project."

To our knowledge, ADOT has not issued a final design plan or begun ROW acquisition. However, in the event that project is funded and proceeds, and in the event the final design calls for condemnation of some of our property, as indicated in our proposal at page 21, we would maintain visual screening in compliance with MSB 17.60.110 by either moving the earthen berm, or installing a continuous, solid fence, depending on how much land was condemned. To the extent the final ADOT plans call for condemning an amount of land that would encroach on the proposed area of the monofill itself, we would reduce the size of the monofill accordingly, leaving adequate land to be able to maintain code compliant visual screening. We would not expand any of the other boundaries. To the extent the final ADOT plans conflict with our proposed entrance, we would, in consultation with and approval of ADOT, move the entrance to allow for the most efficient and safe traffic flow.

6. "Provide a copy of the wetlands review performed by Hemlock Scientific, as addressed on Page 15 of 38 of the application material."

As requested the Hemlock Scientific wetland review is attached, Attachment 9.

7. "Page 16 of 38 states "Water level data is being shared with Alaska Department of Natural Resources for regional study of ground water table elevations". Provide a copy of all water level data that you have submitted to ADNR in regard to this project."

CMS has authorized ADNR access to the existing groundwater monitoring wells. ADNR is measuring water levels and collecting data from these wells. Any water level data taken by ADNR has not been provided to CMS to date. Water level data taken by CMS is contained within the Maddox document Attachment B and Attachment G of our original submission. An updated water level table is also included in EMI's response, Attachment 1, described in response to question 1.

8. "Page 17 of 38 states "Alaska Department of Environmental Conservation (ADEC) reviewed the CMS Monofill Permit application for this site and has approved the permit conditioned upon receipt of the MSB CUP". ADEC has indicated to the borough that the permit has not been approved (See attached e-mail from ADEC). Please clarify and provide a copy of any approved ADEC permit."

As stated in your email of January 22, 2014 from Lori Aldrich, ADEC has reviewed the application and determined it met the requirements for an inert monofill, this led to them posting public notice. On April 15th, 2013 we received the attached email from Nathaniel Emery with ADEC that stated, "I spoke with the MatSu Borough and looks like their process is much further out. Because you can't do much without their green light, we probably won't race to issue this permit but so far we feel the application is complete and nobody has presented any information for us to be suspicious of the proposal." Both emails agree that we have met the requirements of an inert monofill. ADEC could issue the permit but it would be conditioned upon having any locally required permits, in this case the MSB CUP. The ADEC permit has not been written, however we have confirmation from both of these ADEC staff that our application meets the requirements for an inert monofill and has been through the public comment period. See Attachment 10. The MSB CUP can be granted with it conditioned upon having the final ADEC permit.

9. "Page 21 of 38 states "The adjoining residential lots are screened from view of the property by trees". Page 28 of 38 states "The vegetation that is remaining on site is the forest located along the top of the mined banks and helps create a visual barrier between the public and the CUP activities. The existing trees will he left in place and used as a visual and noise buffer". The monofill goes to the top of the bluff. It is not appropriate to use adjacent properties for the buffer. Any buffer should be located on your property. Provide a plan for buffering the neighboring properties as the monofill is built up and out towards those properties."

All buffering is on CMS property, page 21 of 38 under Visual screening states, "The adjoining residential lots are screened from view of the property by trees." The visual screening trees are on CMS property. The property line is surveyed and is located in the trees. The CMS trees were left along the property line

by the prior property owner for the same reason, to screen the property for material extraction. Page A-3 Existing Conditions and Page A-4 Site plan show the property line along the top of the bluff. Please see Page 20-21 and 28 of 38 as well as Drawings; Page A-5 Typical Sections, Page A-7 Operations Plan and Page A-8 Cross Sections for the plan submitted to provide additional buffering when the fill exceeds the height of the existing terrain. This additional buffering is constructed when the cell berms are built. These buffers are all on CMS property. The final height of the fill does not exceed the height of the trees along most of the western property boundary adjoining residential lots. Also see paragraph 3 on Page 27 of 38. Attachment 7 is a revised sheet 6 to further clarify. Please replace page A-8 in our original CUP package with Attachment 7 a revised drawing. Per 17.60 screening is only required to the public ROW which for this site is only the southern property line along the Glenn highway.

This picture shows the Anchorage Regional Landfill along the Glenn Highway where closed cells exceed the height of surrounding trees. This is an example of the proposed visual screening. A vegetated slope creates the visual screening from the highway when the facility grows over the trees. For reference a photo of the proposed CMS site is shown on page 20 of 38 in the CUP application package.

For reference the above photo is an aerial of the Anchorage Regional Landfill that depicts the magnitude of that landfill and how it is screened from view of the public ROW in the preceding image.

10. *"Page 22 of 38 states "per the ADEC permit municipal and household waste will not he accepted at the facility". Provide a specific list of materials that can be accepted at the facility. For example, are the following items part of the residual material being deposited in the monofill: pressure treated wood, containers that contain residual materials, drywall, lead paint, formaldehyde containing materials, glues, mastics, and adhesives. What is the volume of residual material accepted? Are residues not considered hazardous due to their volume compared to the total cumulative volume?"*

Materials that can be accepted by this monofill are described in the State of Alaska's Solid Waste regulations, 18 AAC 60. (Attachment 11) It is not practical to provide a specific list of materials that can be accepted. Nearly everything used to construct a building is included. For example dried glues, mastics and adhesives are included as part of demolition debris, as well as hundreds of other materials used in the construction of buildings. All these materials will be accepted at the monofill in limited

quantities, and it would be near impossible to list all of the combinations of material. All of the material brought in will be considered inert non-hazardous residual material. Prohibited items are listed on page 5 of 12 of the facility Operations Plan that was submitted to ADEC for approval. See Attachment 12. Liquid wastes are not accepted at CRS or CMS. Containers of paint, glue, adhesive, wood preservative etc. are not accepted for disposal.

For comparison see the Attachment 13 "Acceptable Waste Policy" for the MSB Central Landfill. Construction and Demolition (C&D) debris is defined for the MSB Central Landfill as *"C & D is waste material generated during the construction or demolition of a structure. This typically includes wood, bricks, rubble, drywall, roofing materials, tiles and concrete."* and shown in Attachment 14. Theses described C&D debris are placed in an unlined monofill at the Central Landfill which was designed to the same standards as the proposed CMS facility.

Concerns raised of Formaldehyde containing materials are addressed in Attachment 3, page 9, but were found to rapidly biodegrade and not be of concern.

See also Attachment 22 for a characterization of C&D debris prepared for the EPA.

11. "Page 22 of 38 states "Loads hauled into the facility that have not been previously inspected by CRS personnel will be dumped onto a lined pad for inspection". Page 35 of 38, #4, also states "All waste delivered directly to the monofill is first placed within a lined area and inspected". Page 29 Sequence of Fill does not address the separate inspection area. It states that trucks will place their loads in the operational cell. Page 37 of 38, # 12, does not discuss this lined inspection pit as a non-permeable surface at the site. Clarify these inconsistencies and explain what is the actual process. Is the lined pad non-permeable? In addition, will this inspection pad be moved around the site or will it remain in the same place so that it can be shown on the site plan?"

Page 29 Sequence of Fill does not address the inspection pad as this paragraph is intended to cover the construction of the cells and not necessarily the flow of the material getting to the cells. The truck dumping in the cell per Sequence of fill could be a truck hauling from the recycle facility that was previously inspected or a load hauled from the inspection pad on site.

To clarify, there would be two waste streams entering the facility. One stream is the material hauled from a CRS operation that has already been inspected and processed. The second waste stream is material hauled from known customers that has not yet been inspected by CRS. See Attachment M, page 28 of the CUP application for this flow process and re-attached to this response as Attachment 21. Materials that have not been previously inspected are initially dumped on the impermeable inspection pad where they are inspected, recyclable material is removed and remaining non-recyclable material placed in the active monofill cell. Upon inspection, if prohibited materials are found they will be properly segregated from the waste, packaged for transport and disposed of at a properly permitted facility. Any

contamination of the soil cover on the inspection pad will be tested and cleaned up as part of the prohibited material removal. The cost for the cleanup and testing is passed onto the customer.

Page 37 of 38, #12 was intended to indicate the permanently placed impermeable surfaces. Such as paved parking areas. The impermeable inspection pad will be moved as needed during operations of the monofill and considered temporary. This could be added to the areas discussed under #12 if the MSB intent was for this to cover all impermeable surfaces.

The last sentence of Paragraph 3, page 22 of 38 states "This inspection pad will be near the working area of the landfill and relocated as the cells and working area move within the monofill."

12. Page 22 of 38 discusses the inspection pad that will be capped with 2" of soil. What is the plan for disposal of this soil? Will this soil be tested prior to its disposal or use? What is the plan for managing the run-off coming from the inspection area?"

The inspection pad will be an active operation. If something is dumped on it that could contaminate the soil it will be found during the inspection process and properly removed and cleaned up. At this point the customer that delivered the prohibited material would be charged the cleanup cost. This active process of inspection and cleanup will maintain the soil in a clean condition such that when it comes time to move the inspection pad, the capping soil could be used elsewhere in the facility for berms or intermediate cover without further testing.

An example of this process would be if a roll off container was dumped on the inspection pad and the inspector found bags of household trash. These bags and any affected soil would be immediately removed from the inspection pad to a municipal waste dumpster for proper disposal at an offsite MSW Landfill and the customer charged.

Run off from the inspection pad would be no different than the natural process elsewhere on the monofill. The inspection pad is maintained in a clean state with no prohibited materials allowed to remain on the pad, keeping any water on the inspection pad from being contaminated.

13. "Page 22 of 38 discusses the careful handling of "hazardous wastes". The proposed monofill proposes to exclude "hazardous waste". It is not clear what this means and in particular, that all waste that may be hazardous to water supplies will be excluded. Provide a specific list of everything that is tested for in the Building Material Survey."

A typical Hazardous Building Material Survey checks for all potentially hazardous building materials that should be identified and, if required by regulators, removed prior to demolition. Suspect items typically include the following materials:

- Items coated with lead based paint

- asbestos in insulation, ceiling or floor tiles, and grout
- mercury in switches, thermostats, electronics, fluorescent bulbs and other equipment
- chlorofluorocarbons (CFCs) or other harmful chemicals in old refrigerators, air conditioners and aerosol cans
- polychlorinated biphenyls (PCBs) in transformers, lubricants, paints, and sealants
- radioactive sources such as exit signs
- potentially toxic household or agricultural chemicals, including certain paints, cleaning products and pesticides
- if the building has unusual equipment or materials stored in drums or tanks, these would be removed or checked for hazardous materials before demolition

Page 22 of 38, Health and Safety review discusses materials that are not supposed to be delivered or disposed of at the CMS facility but shows measures are in place to inspect loads and remove these materials so they are not improperly handled or disposed of.

14. "Page 22 of 38 states that CRS and CMS have specific policies outlined in the Operations Plan. Provide a copy of the CRS and CMS Operations Plan."

A copy of the Operations Plan for this Facility is attached. See Attachment 12.

15. "Pages 22 -23 of 38 states in part "suspect materials delivered to CRS are tested and, if found, removed from the waste stream... ". What criteria will be used to determine suspect materials?"

There are a variety of things that could cause a material to be suspect. In addition to Asbestos Inspectors Certification, inspectors will be certified as Hazardous Waste Operations and Emergency Response - First Responder Awareness Level under 29 CFR 1910.120. The training for this certification includes all the topics listed in the regulation such as recognition of suspect materials, the health hazards associated with those materials, and initiating the appropriate response to the situation. Annual refresher training is required to keep this certification current. Additionally when a customer provides a Hazardous Building Material Survey (HBMS) for a demolition load, and a required certification of removal, the HBMS is used to identify suspect materials to look for in that customer's loads to verify they were in fact removed. See Attachment A, Page 10 of the CUP application for a process drawing.

16. "Page 23 of 38 states "suspect material will be tested in accordance with regulatory required test methods to identify hazardous materials content, if any". How regularly will Toxicity Characteristic Leaching Procedure (TCLP) occur? Does visually seeing paint make it "suspect"? Will any materials with lead paint be accepted?"

There are many factors that contribute to the decision of when TCLP tests will be conducted. The age of the facility and the results of the hazardous building materials survey are the two primary factors in determining if a TCLP is warranted. Production of lead-based paints were restricted by the Consumer

Product Safety Commission in 1978. Therefore old buildings constructed before that time will be checked more carefully for lead-based paint. Materials from a new building may not be checked for lead based paint because of the low likelihood of the paint being present. Any building that has lead-based paint identified in the hazardous building materials survey will have a TCLP test completed on the waste. If the concentration of lead is not considered hazardous, based on the federal standards listed in 40 CFR 261, then this limited quantity of lead-based paint will be accepted at this monofill. If the concentration is too high, the material will not be accepted unless the lead based paint is removed and the material retested for verification.

17. "Page 23 of 38 regarding asbestos. Asbestos will be placed in plastic bags which heavy equipment can perforate. Asbestos does not dissolve, however, it does become easily airborne. The fences proposed to stop blowing trash on a windy day will do nothing to stop asbestos. What type of fence will surround the asbestos cell? What is your policy for handling RACM during the wind?"

Please carefully read the second paragraph on Page 23 of 38 and item 9, Page 36 of 38. The difference in RACM and Non-RACM is important.

Per federal regulation RACM is packaged in double bags and placed in a manner, in the RACM asbestos cell, as to not compromise the integrity of the packaging. This may be by hand, pallets placed with a forklift, etc. Once placed in the cell the cover soil is placed in a manner that the equipment does not contact the packaging. The soil is placed to protect the packaging. The RACM cell is fenced with chain link. The RACM will never be exposed to the air or wind to be blown. This would be a violation of federal regulations.

Non-RACM has the asbestos bound within a matrix that prevents it from becoming air borne. An example of Non-RACM is a glue or mastic on concrete. Unless it is mechanically being removed from the concrete it can't become airborne. This material is delivered in a damp state, placed and covered daily.

For comparison see Attachment 18, page 3 for the MSB Central Landfill requirements for Asbestos Cell requirements.

Per page 18 of 38, if winds exceed sustained 20 mph, material will not be dumped at the monofill.

18. "Page 30 of 38 states "Other materials deposited into the monofill are placed within the cells and will be covered intermittently, however, not necessarily daily". Page 18 of 38 states "Regularly covering the waste with soil further prevents blowing debris". What is meant by "covered intermittently" and "regularly covering"?"

As stated in the fourth paragraph page 30 of 38, per the ADEC permit RACM and Non-RACM is covered daily, "other" materials will be covered as needed. Some materials will be susceptible to blowing and others would not. For example chunks of concrete could be left uncovered for months with no danger

of creating blowing debris and could actually be used as cover of other materials more susceptible to blowing. Materials with a lot of loose light components or sheets of materials would be very susceptible to blowing and may need to be covered daily. Therefore we used the term "covered intermittently" to describe materials being covered daily to weekly or intermittently as needed. Page 18 of 38 "regularly covering" is in the context of keeping things covered to reduce blowing debris. Any covering weekly would be regular covering. This may be supplemented with "cover intermittently", less than the regular weekly cover. For comparison see Attachment 18 and the permit requirement for the MSB Central Landfill to cover the C&D material monthly.

19. "Page 31 of 38 states "the ADEC permit requires the owner to provide bonding or other financial assurance to cover the cost of monofill closure ". CMS also claims that it has "sufficient Environmental and Pollution Insurance to cover this project". Provide copies of the bond, insurance policy and certificate of insurance."

Policies specific to this facility will not be provided until issuance of the CUP. There is a substantial cost to pay for the bond and insurance for this facility and it would be unreasonable to pay for these before issuance of the CUP. The Bond will be in the amount required by ADEC. E&P insurance will be $1 million single with a minimum $5 million aggregate. See Attachment 15 for a sample copy of a CMS certificate of insurance.

20. *"Page 34 of 38 Hours of Operation. How will CMS be handling hours of operation during the Alaska State Fair?"*

CMS will coordinate with the State Fair and be flexible to curtail operations during the fair as to not impede fair traffic or delay our trucks. It is unreasonable at this time to place any specific conditions on this as we can't forecast how future highway capacity improvements, traffic routing or other factors may affect traffic during the fair.

21. *"What will be the actual maximum height of the finished monofill above the bottom of the cell?"*

See page A-8 Palmer Monofill Cross Sections that shows the maximum finished elevation of the monofill at 162' Above Sea Level. For reference the adjacent Glenn Highway has an average finish elevation of 117' Above Sea Level, so the maximum height will be a little more than 40 feet above the Glenn Highway. The existing tree covered berm along the Glenn Highway has an average elevation of 130' Above Sea Level, with 20' and taller trees growing on top of that. If you are asking what the maximum depth of the monofill is, it would be 75' with an average depth of 50'. The max height of any individual sub cell is 15'.

22. "What is the maximum square footage that will be exposed and not covered at any one time during the operation of the monofill?

25,000 square feet

23. "Has the site been evaluated for impacts that would occur from a large earthquake, including, but not limited to susceptibility to liquefaction, potential changes in hydrology, i.e. raised water levels, and impacts on the tire bale structure?

Yes, seismic evaluations of the site have been completed. Attachment 16. Northern Geotechnical Engineering, Inc. (NGE) has completed a seismic analysis showing the monofill structure can be constructed to be seismically stable with slopes as steep as 1.2H:1V using tire bales and geogrid. They also evaluated the shallower slope of 2H:1V slope used in the design for this project which will be more stable. See Attachment 16. The existing site is not vulnerable to significant impacts from a large earthquake due to topography, soil types or ground water. The ground water is below the relatively flat bottom of the monofill, so there are no saturated soils that could liquefy and the flat bottom does not have areas for material to slough to. The monofill is designed with setbacks keeping the monofill away from the ponds so even if a slope were to fail the waste material would not reach the ponds.

The AlaskChem Engineering report referenced in the response to #1 evaluates changes in hydrology and water levels in the area from the 1964 earthquake. While there were significant short term impacts to some wells in the general area, there were no long term changes attributable to the earthquake.
The Brailey Hydrologic Consultants, Groundwater Modeling Report for Anchorage Sand & Gravel was also reviewed, Attachment 20. The modeling performed for future mining activities adjacent to the proposed site does not show any long term adverse impacts to the proposed CMS site.

24. *"What is the fire preparedness plan for this site? What would the impacts from a fire and how would you address them?"*

See the Fire Risk section page 17 of 38 of the CUP application and the Operations plan Attachment 12. In the unlikely event of a fire heavy equipment on site can be used to expose a fire by digging it out or to place soil over a fire to starve it out. A pump and hose will be on site in the event of the need to pump water on a fire. A 10,000 gallon water storage tank is staged on site. All trucks, equipment and recycle facilities at the proposed site will be equipped with fire extinguishers.

The impacts of a fire on the monofill would be minimal. The monofill as designed has fire breaks around the sub cells that would keep a fire from spreading beyond a single sub cell within the site. As designed the monofill has more than 32 separate cells each of which will be constructed from multiple smaller sub cells. See Page A-7, A-8, A-9 drawings for cell layout and pages 28-30 for monofill construction plan.

The health hazards associated with a house or other building fire are far worse than a fire in the proposed monofill. Although the material in the monofill is generally used building material, the same as what you would find in a common building, the waste placed in the proposed monofill is inspected, screened and processed removing any flammable liquids, explosive materials, hazardous waste or other highly combustible materials that are common to a residence or commercial structure. The waste in this monofill is tightly compacted with very little oxygen or air movement which would burn slow allowing it to be extinguished before it spreads. A fire in this monofill would present much less risk than a normal structure fire where flammable liquids, ammunition, etc. could be present.

25. "Based on the application material and information in the February 7, 2014 Munter report, staff has determined that a Core Area Conditional Use Permit is required, per the requirements of MSB 17.61. Page 3 of 14 of Munter's report states in part "...it would be reasonable to assume that there will be a sufficient amount of waste accumulated to generate leachate that will exceed one or more drinking water Maximum Contaminant Levels." In addition the report states in part "...it is highly likely to result in measurable increases in contaminants beneath the facility and/or some distance down gradient." A Core Area Conditional Use Permit application form is attached for your use."

Based on our previous meetings with staff and analysis of the Code it was determined that the 17.61 Core Area Permit was not required. The proposed operation does not handle materials in regulated quantities over any of the thresholds listed in 17.61 that would trigger the requirement for a 17.61 application.

The Munter report makes unsubstantiated assumptions that contradict actual calculated data in the attached reports performed by subject experts. We fail to see where any of Munters opinions or assumptions trigger any MSB requirements of a Core Area Permit. The Maddox report and other expert opinions attached contradict Munter's assumption with calculated data showing no contaminated water runoff or other discharges that are likely to violate state water quality standards or negatively impact groundwater or surface water quality beyond adjacent property lines.

ADEC Solid Waste Program regulations and standards were developed specifically to, as stated in the ADEC mission statement, "Conserving, improving and protecting Alaska's natural resources and environment to enhance the health, safety, economic and social well-being of Alaskans." More specifically the mission statement for the ADEC, Solid Waste Program states: "We are committed to protecting public Health and the environment through ensuring effective solid waste management, which includes landfills, treatment systems, and solid waste storage facilities." The proposed recycle facility and monofill are designed to these standards and as evidenced by the attachments meets these standards. The Munter assumptions and apparent MSB position that this facility possesses a health risk contradicts an entire state agency, with a specific program, that is charged with regulating landfills and further contradicts the findings of four subject matter experts whose reports are attached.

17.61.100(B) Activities excluded from conditional use permit requirements under this chapter include: (7) building materials

If this determination was made based on Munters comments paragraph 2, page 12 of 14, then it should be disregarded. "In response to the question: Will the granting of the conditional use permit be harmful to the public health, safety, convenience and welfare?(page 1 of 3 of the MSB CUP application), the applicant answered "yes"." Munter is in error as that yes as entered in the form only signifies "yes" that an explanation is attached.

A 17.61 application would not be consistent with prior 17.60 CUPs that have been granted by the MSB and were discussed with MSB staff prior to submission. An example discussed was the Tri-Metal 17.60 CUP for a facility located off Knik Goose Bay Road, Attachment 19. This facility proposed to store and process scrap metals, building materials etc. This site, located along Knik Arm, adjoins the water. Similar health and safety concerns were raised during public comment at the CUP hearing and were not found to be sufficient grounds to trigger a 17.61 application. The Tri-Metal 17.60 CUP for a similar operation at a very environmentally sensitive site was granted without the conjecture and assumptions being made of the CMS application.

26. "Staff is currently researching whether or not the tire bale walls and monofill constitute a structure and are subject to the setback requirements in MSB 17.55 -Setbacks. We will forward our determination to you as soon as it is complete."

Per 17.55.004 Definitions "the following are not considered structures unless specifically addressed by code: fences; retaining walls..." The Tire Bales are used within the facility as retaining walls to reinforce slopes around the facility. Slope stability analysis of these retaining walls was performed and attached as Attachment 16. Per ADEC requirements waste material that makes up the monofill is maintained at a minimum of 50' setback from the property line.

The additional review, engineering and modeling performed by experts in this field and attached has determined that there will possibly be no Leachate generated let alone contaminated leachate leaving the site. Further the review found other similar monofill sites in Alaska that were monitored and had higher risk waste buried within that have not generated contaminated leachate. This supports the ADEC regulations that do not require ground water monitoring for an inert material monofill. For this reason CMS is removing the ground water monitoring program from our application. Please insert Attachment 17 as replacement to page 16 in our original CUP application package, also remove Attachment N. further, Attachment 5 replaces page A-2 and Attachment 7 replaces page A-8.

The MSB does not have building codes let alone landfill/monofill codes. The ADEC has developed the standards this facility has been designed to, based upon Alaska climatology and geology.

The proposed CMS recycle facility and monofill meets the MSB 17.60 requirements as shown on pages 31 thru 34 of our original CUP application and further supported with the multitude of pages of additional documents. Assertions made by the MSB consultant, Munter, about the health and safety impacts of the monofill are refuted with facts in the attached documents that show issuance of the CUP will not be harmful to public health and safety. For Munter to say that this monofill as designed and proposed is a health hazard is opinion, not fact based and contradicts without support ADEC/EPA regulations as well as established professional models.

The MSB operates a monofill designed and constructed to the same ADEC standards, but operated with much less control of the incoming waste than the proposed CMS facility. See Attachment 18 for a copy of the MSB Solid Waste permit, November 19, 2010 for the Central Landfill lined Municipal Waste Cell and unlined C&D cell. Assertions that the CMS facility will be a health hazard would mean the MSB facility is a health hazard which is not the case. The attached review by AlaskChem Engineering which includes the study of water test results from the MSB Central Landfill further substantiates the ADEC design standards are appropriate to this locale. The Central Landfill operated unlined Municipal Waste cells in the 80's and 90's which are now closed and still unlined. Recent groundwater monitoring of this site shows no concentrations exceeding groundwater protection standards.

Attached are reviews/responses from two Professional Engineers and two Professional Geologists considered experts in the respective fields and their substantial supporting data. Their conclusions include;

- "this monofill was designed to meet the established state and federal codes which were developed to protect both human health and the environment."
- "the proposed monofill will not pose a threat to the underlying aquifer."
- "In conclusion, the proposed monofill appears to be protective of groundwater sources if the monofill is constructed as modeled in the conceptual model."
- "the proposed monofill will not cause recognized adverse health impacts from contamination of groundwater."
- "The CMS system appears to be superior to other current C&D monofill systems for its ability to further reduce lifecycle health risks and enhance end use value."

The neighbors may not like the stigma associated with the waste and recycling business, but current design standards, state and federal regulations, conceptual models, engineering and historical data all show this CUP can be granted without adverse impacts to the public or environment.

The information needed for MSB staff to support our CUP application has been provided but may need further clarification for staff due to the technical nature of this information. This is a likely reason why the State of Alaska has a special program to manage solid waste so that every local agency does not

have to be an expert in the field. CMS respectfully requests a meeting with MSB staff and our subject matter experts to go through this information and address any further concerns you may have.

Hopefully, this response clarifies our CUP application and answers your questions. I can be reached by cell at 350-6062 or email shane@cei-alaska.com if any further questions exist.

Sincerely,

Shane Durand

RE: Central Monofill Services Conditional Use Permit Application, CMS Recycling Facility, Palmer, Alaska

Subj: Response to Matanuska-Susitna Borough's Request for More Information

This letter is in response to Matanuska-Susitna Borough's (MSB) request for more information dated February 13, 2014. In that letter they requested the issues raised in J.A. Munter Consulting, Inc.'s February 7, 2014, report be addressed. Mr. Munter raised a lot of concerns. I am responding as the engineer in responsible charge of the design of the monofill and so will address the concerns raised by Mr. Munter where I am most qualified to respond.

First off, I want to clearly state that this monofill was designed to meet the established state and federal codes which were developed to protect both human health and the environment. Mr. Munter developed a report that implies more stringent but unspecified standards are required, uses illogical arguments, and presents a strong bias and obstructionist attitude against the monofill. While he may have some valid points they are lost in the bias demonstrated throughout the report. The following comments address some of his issues in more detail.

In order to construct and manage landfills in a practical manner, the regulatory agencies have established specific design standards depending on the toxicity and potential hazards associated with the waste placed in the landfill. It is not reasonable or practical for a government to require all wastes be placed in a landfill that can safely contain all types of toxic and hazardous wastes. For example, because of the stringent standards required for landfills to safely dispose of hazardous waste, there are no RCRA Subtitle C hazardous waste landfills in the State of Alaska. As another example the municipal waste part of the Central Landfill is lined but the inert waste part is not lined. In my professional opinion, it is only appropriate to evaluate this landfill against the standards that are in place to regulate inert landfills. Mr. Munter seems to disagree with this approach to landfill design. He implies the current standards are not appropriate for inert waste disposal but does not offer any alternative standards to use. For example on page 6 he states, *"In this situation, if the MSB decides, after an appropriate decision-making process, that sulfate levels are important to local well owners, then it would not seem to make any difference what the USEPA thinks is suitable for public water systems."* Mr. Munter's statement implies that the established standards may not be acceptable or appropriate for the design of this monofill, and the implication is the Borough should not approve any inert monofill until appropriate standards are established by MSB or some developer designs a landfill to meet Mr. Munter's unknown and unspecified

www.emi-alaska.com

standards. The design and planned operations of this monofill have gone beyond the minimum regulatory requirements in order to provide a safe system to store inert wastes. It is interesting to note that while he states on page 2 of his report, "*At least 27 states now require groundwater monitoring from such landfills in increasing recognition of their potential to contaminate groundwater,*" Mr. Munter ignores Alaska's ground monitoring requirements. Alaska is often listed as one of states that require ground water monitoring, since they require ground water monitoring of inert landfills when there is significant rainfall in the area. I think his approach and wording in his review presents a strong negative bias towards the monofill.

Another example of an apparent bias is Mr. Munter's approach towards Mr. Maddox. Due to the Borough's previously expressed concerns about the Alaska established standards not being sufficient (for example the 10 foot of separation from the ground water to the monofill), Central Monofill Services (CMS) hired an expert in landfill design and assessment, to review my design for this monofill. They found Mr. Steve Maddox, a certified professional geologist and hydrogeologist with several years' experience doing assessments at more than 50 landfills. He was contracted to conduct an independent review of the design. Mr. Munter's report primarily focused on the Maddox and Associates, Inc. report which evaluated this submitted monofill design with respect to the potential impacts to the ground water. Mr. Munter's apparent bias against Mr. Maddox shows up on the first page of his report where he seems critical of Mr. Maddox for not doing a site visit from California as part of his review. While site visits can be helpful, Mr. Maddox's task was to review the available data. Mr. Maddox was not hired for his expertise in Alaska. I have been practicing environmental engineering in Alaska for over twenty years, and have completed designs on multiple landfills. Since the Alaska standards were placed in doubt, CMS thought it would be appropriate to have an expert with experiences at multiple landfills and in many regions of the country to review our design. Rather than complete an unbiased review of Mr. Maddox's findings, Mr. Munter tries to discredit him at the start.

His next point on the first page is another attempt to discredit Mr. Maddox by presenting an irrelevant argument. He raised a concern that the site conceptual model Mr. Maddox developed to help evaluate the landfill site, does not meet the Alaska Department of Environmental Conservations (ADEC) guidelines for developing a Conceptual Site Model (CSM) for evaluating contaminated sites. Conceptual models are commonly used by professionals throughout the engineering and science fields to help understand what is happening in a particular situation. The value of a site conceptual model is based on the use of sound modeling principals in developing and applying the results of the model. ADEC's CSM guidelines were developed for the specific purpose of helping ADEC project managers better understand the characteristics of a contaminated site. Mr. Munter's implication that Mr. Maddox's model is not valid because it does not follow ADEC's guidelines is totally unfounded. Either Mr. Munter has a personal agenda or he is not able to see the difference between two valid modeling paradigms. (Note Logic texts have a specific term for the practice of comparing two unrelated models and then subsequently tearing down one model (Maddox's SCM) against the concepts and regulations of the other (ADECs CSM). It is called a "Straw Man" argument. A fallacy that occurs when the arguer misinterprets an opponent's position for the purpose of more easily attacking it, demolishes the misinterpreted argument, and then proceeds to conclude that the original argument has been demolished. I don't know if Mr. Munter is intentionally using a "Straw Man" or if he is unaware of the

www.emi-alaska.com

details of what he is talking about.) Having presented this basic background describing my concern of Mr. Munter's apparent bias, I will go on to address some of the specific issues Mr. Munter has raised.

Use of the Terms Hazardous and Inert: Mr. Munter makes the point that there are multiple definitions of these terms depending on who is using them and in what context they are being used. I agree. For example, a mother with a 3-year old would likely consider a 2x4 with shape nails sticking out hazardous for her child to play with. While this might seem to be an absurd example of what might be considered hazardous when we are talking about construction debris, it makes the point that these terms need to be appropriately defined if we are going to use them in our design or in the review of the design. Without using a common definition of the terms, statements like Mr. Munter's on page 3: "*it is difficult for the Borough to know or be assured that all materials that are potentially hazardous are appropriately excluded*" are generalizations that have no valid practical meaning. There will be 2x4's with sharp nails in the in the waste. That fact that someone considers 2x4's with sharp nails as being potentially hazardous, does not mean that it is hazardous waste. To avoid confusion and since we are dealing with waste here, I think the most appropriate definitions of these terms come from the regulations that have been promulgated to ensure proper handling of waste.

The Alaska Statutes Sec. 46.03.900 has the following definition for hazardous waste:

(9) "hazardous waste" means a waste or combination of wastes that because of quantity, concentration, or physical, chemical, or infectious characteristics may

(A) cause, or significantly contribute to, an increase in mortality or an increase in serious irreversible or incapacitating reversible illness; or

(B) pose a substantial present or potential hazard to human health or the environment when improperly managed, treated, stored, transported, or disposed of;

The federal regulations define hazardous waste in 40 CFR 261.3 by listing the specific criteria that should be used to determine if a waste is hazardous or not. The federal definition is specific enough that a waste can be evaluated against legal standards to determine if it is a hazardous waste or not and therefore is the most common legal definition used in the United States.

The Alaska definition is more vague and open to interpretation on what is considered "substantial." I think everyone will agree that a 2x4 with a sharp nail would not pose a "substantial" present or future hazard to human health and therefore should not be considered hazardous waste. However, in more complex situations a more specific definition is needed. The federal definition in the regulations more clearly defines specific characteristics of wastes that will be a substantial hazard to human health and the environment. The submitted operational procedures developed for this landfill as described in the submitted plan will prevent hazardous waste, as defined by the federal government, from being placed in the landfill.

Mr. Munter also has issues with use of the term inert. He says that the definition used by Mr. Maddox for "inert waste" is reasonable but then goes on to express concern with this definition. On page 2 he says that inert waste materials put in the landfill will eventually rot, decay, and leach, implying they are not inert. While this may or may not be a true statement, it is hard to dispute because of his use of the term eventually. It is hard for someone to predict what will happen to those materials in tens, hundreds or even thousands of years. Without significant levels of moisture in the landfill, the rate of rot and decay will be very slow. The landfill is designed to minimize the moisture levels in the material, so that the rate of decay and rot will be very slow and will not significantly impact any leachate, if there is any leachate at all that leaves the monofill. Many of the materials placed in the landfill will likely still be around hundreds of years from now in a similar form to what they were when originally placed in the monofill.

CRS Residual Material Sample Testing Results: Mr. Munter is incorrect on how to interpret the results of the testing that was completed on the residual material generated at the CRS processing facility. He implied that the results could be used to represent the leachate coming from the landfill and that this leachate could be directly, without any dilution, found in a drinking water well over 500 feet down gradient from the monofill. The implications he presented are very misleading.

We elected to use the Synthetic Precipitation Leaching Procedure (SPLP) to check for potential contaminates of concern from the waste. SPLP is a well-established testing procedure that is an EPA approved method to test wastes. Mr. Munter seemed concerned that this well established method has limits of quantification that are above EPA's Maximum Contaminant Levels (MCL) for drinking water. The method is not designed to test water for drinking standards. It is designed to identify contaminates that may be of potential concern in waste water. In some states these results can be compared to that state's risk based standards to see if the material can be left in the ground indefinitely without imposing a risk to human health and the environment. Alaska does not have any established standards to directly compare with the SPLP results, therefore the results should not be used in a direct comparison to any specific Alaska standard. As my earlier remarks suggested either Mr. Munter is not familiar with current industry standards and is unaware of this EPA approved testing procedure or he has a distinct agenda and is a biased reviewer. The University of Florida, conducted a study to determine the risk of metals leaching from the fine residue from C&D recycling operations similar to ones the CRS is running. In the study 46 SPLP tests were completed on samples from 13 different facilities. The conclusion of the SPLP testing in the study was that none of the results exceeded Florida's Risk Based water quality standards. (Townsend, 2004) Please note that the SPLP results in the study did exceed federal drinking water standards; however, SPLP results should not be compared directly to drinking water standards.

I am providing the following summary of the SPLP testing procedure to help everyone understand how to interpret those results. In order to maximize the leaching potential from the waste and hence identify compounds of potential concern, the SPLP procedure requires the waste be reduced in size to particles that are less than 1 cm. (Note that this is the same size reduction procedure that is required for the more common Toxic Characteristic Leaching

Procedure (TCLP) which is used to test materials to determine if they are hazardous.) For example, a small piece of demolition material that is 6"x2"x4" must be reduced in size to pieces smaller than 1 cm in any dimension. The exposed surface area of this material is increased by close to a 1000 times by this process, creating a significant increase in the rate of leaching. This material is then placed in a container of acidic water and agitated for 18 hours to further enhance any potential leaching that might occur. This water is then tested for various compounds of concern to see if any have leached out of the material and into the liquid. In other words, the SPLP test determines what compounds have a potential to leach in an acidic saturated environment that is being continually agitated. This landfill has been specifically designed so that the waste will never stay in a saturated condition, so it is unfounded and unrealistic to say the SPLP results would represent the leachate from the monofill.

He presents another unrealistic interpretation on page 3 when he says that if this artificially created leachate with a sulfate level of close to 600 mg/L appeared in a well, it would be a problem to that well owner. While this statement by itself is true, it also implies that this leachate could come from the monofill magically appearing in a drinking water well several feet away. I know of no way in the real world where a leachate could be transported by nature at full strength to a well more than 500 feet away. Mr. Munter appears to be comparing unrelated data and standards in an unscientific manner in order to influence uninformed readers.

Water Monitoring Plan : CMS provided a practical ground water monitoring plan to verify that the monofill is not impacting the ground water. The plan was developed using detection monitoring principles that are described in ASTM, EPA and ADEC documents. Mr. Munter raised several concerns about the plan, which may be valid if this was a municipal waste landfill. However, I am not sure if any monitoring plan for this landfill would satisfy him. Based on further review of the site specific conditions by the hydrologists, we have found the probability of creating a leachate that will impact the ground water is so low that ground water monitoring is not necessary. Therefore I recommend the submitted ground monitoring plan be withdrawn and not implemented.

Design of the Bottom of the Cells: Mr. Munter expressed concern that a seasonal high water table has not been established for the site. We have water level data from all four seasons with over 20 events covering April 24, 2013, to April 15, 2014. We plan to continue to collect water data, continually updating our data set. The bottom of the monofill cells will be established based on all of the water data we have collected up to the time of construction of that cell. The seasonal high water table shown on Figure 6 (page A-8 in application package) is based on all the water data collected through April 15, 2014. This will be used for final design for construction unless a higher water table is measured between now and the time of construction. By the time of construction we will have more than a full year of monitoring data available for review.

In conclusion, I find it interesting that Mr. Munter claims Mr. Maddox's conclusions are unfounded and then Mr. Munter makes some very illogical arguments to come to his own conclusions. For example, he first wants us to assume that (1) *"even small percentages of leachable wastes in the 2 million cubic yards of waste will result in measurable quantities of*

206 E. FIREWEED LANE, SUITE 201 • ANCHORAGE, AK 99503-2703
CONSULTING (907) 272-9336 • FAX (907) 272-4159 • TRAINING (907) 272-8852 • FAX (907) 272-0319
www.emi-alaska.com

contamination," in other words he is stating any leachate from the monofill will have measurable quantities of contamination. Mr. Munter than restates the initial assumption with more precise drinking water regulation wording that (2) *"there will be a sufficient amount of waste accumulated to generate leachate that will exceed one or more drinking water Maximum Contaminant Levels."* From these assumptions Mr. Munter makes a concluding assumptive prediction that (3) *"it is highly likely to result in measurable increase in contaminants beneath the facility."* and (4) *"for some distance down gradient."* Mr. Munter assumes 1 and 2 and predicts that 3 and 4 will follow. This is neither a sound argument nor a factual claim, just speculation. When the conclusion of an argument rests on an alleged chain reaction, and there is not sufficient evidence to necessitate the casual links in the argument the arguer is making a slippery slope fallacy -- a fallacy of unfounded induction.

I hope that my response to Mr. Munter's comments and the concerns of the MSB provide a better understanding of the final design criteria used for this inert waste monofill. I have shown the obstructionist and bias of Mr. Munter, through the use of his speculative arguments and in the techniques at which he employs them to further obfuscate the permit application review process. The health and safety concerns of the MSB are my concerns too. We have a vested interest in not allowing hazardous waste into the monofill and to design the monofill to meet the current regulatory standards.

Sincerely,
ENVIRONMENTAL MANAGEMENT, INC.

Larry Helgeson, P.E.
V.P., Consulting

RESPONSE TO SELECTED PORTIONS OF THE J.A. MUNTER CONSULTING, INC. LETTER TO MS. SUSAN LEE, DATED FEBRUARY 7, 2014

The responses in this document will follow the section/page/paragraph structure used by James A. Munter (JAM) in his February 7, 2014 letter to Ms. Susan Lee, of the Planning Department of the Matanuska-Susitna Borough. This is difficult in some places, due to JAM's tendency to jump around and stray from the stated section/subject content.

Some of JAM's comments are not pertinent and there will be no response to them; additionally, some of JAM's comments will be the subject of response by others.

QUALIFYING STATEMENT BY MADDOX & ASSOCIATES:

The primary and most basic contention by James A. Munter Consulting, Inc. is that the proposed monofill will produce large volumes of hazardous leachate that will grossly contaminate the underlying aquifer. The response contained herein to JAM's extensive critique of the Maddox & Associates December 13, 2013 report addresses the bulk of JAM's criticisms, most of which are not of a significant magnitude. One single, major fact is extensively presented and documented herein--that is that the proposed monofill, near Palmer, Alaska is located in a semi-arid climate where the balance between the annual precipitation and the annual evaporation precludes the formation of any significant volume of leachate. Any minor volumes of leachate that may be produced in the monofill will not have the ability to cause a significant impact on the underlying aquifer. Modeling by Mr. Dan Young, of Terrasat Environmental, will be presented separately to substantiate this fact.

On February 18, 2014, Steve Maddox spoke to Ms. Lori Aldrich, of the ADEC, and asked her why the ADEC does not have any problem with the construction of the proposed Palmer monofill. Her primary response was that the monofill met all of ADEC's regulations and based upon the semi-arid climate and the local geology/hydrogeology, they do not expect the monofill to produce significant leachate, or possibly no leachate at all. A complete summary of this conversation is provided on pages 29, 30, and 31 of this document.

PAGE 3 INTRODUCTION

JAM is concerned by the fact that M&A has not worked previously in Alaska. That is true. The simplest response to JAM's criticism is to point out that the majority of our work has been done in Southern California, where, although the temperatures are not similar, the annual precipitation is essentially the same. More to the point, the sediments in Southern California are very similar to those in the Palmer, Alaska area. The comparisons are as follows:

- Palmer sediments: Glacial outwash sediments composed primarily of sands and gravels, transported and laid down by running water (from melting glaciers).

- Southern California sediments: A large portion of the sediments found in Southern California are composed of sands and gravels, typically found in alluvial fans or alluviated lowlands, deposited by running water.

Additionally, M&A has also worked in the following areas containing glacial topography such as is found in the area of the proposed monofill:

- Michigan;
- Ohio;
- Illinois;
- Iowa;
- Washington.

M&A is well-experienced working in sedimentary deposits of all types. We are geologists. We do not need to be in a particular locale to have an effective appreciation and understanding of the nature of the rocks and sediments in that area. To-date, our professional opinion is that a site visit has not been necessary to properly evaluate and reach an understanding of the nature of the geology in the area of the proposed monofill.

SECTION 2.2 SITE CONCEPTUAL MODEL

A response to JAM's criticisms of M&A's Site Conceptual Model is not critical to the decision whether or not to allow construction of the proposed monofill. The sections that follow Section 2.2 are adequate to do so.

PAGE 4 LAST PARAGRAPH

JAM's critique of this portion of the M&A document covers approximately two pages, so each of his pertinent paragraphs will be the subject of our response.

Paragraph 1:

This comparison to other monofills does not take into account that CRS actively removes large quantities of drywall from the waste stream for recycling. It is our understanding that drywall is recycled into soil amendment or animal bedding and used at local farms,. This changes the waste composition from historical monofills that may have had elevated sulfate levels.

At landfills that do not initially remove the drywall from the waste stream, it is true that drywall will decompose if placed in a subsurface landfill environment where significant volumes of water can percolate through it, resulting in the liberation of sulfate. However, as described in considerable detail later in the present document, no significant water will be available to percolate through the inert refuse, nor to "pond" at any level within the refuse mass. Therefore, drywall, if it were to be present in the waste stream at the proposed Palmer monofill, would not degrade and potentially impact the aquifer.

Paragraph 2:

Other constituents that will comprise the inert materials to be deposited with the proposed monofill would leach-out some constituents if subjected to a significant volume of infiltrating or ponding water, but such volumes of percolating water will not be present in the proposed monofill. Other states have significantly different climate and geology fro the proposed site, making additional monitoring necessary. As has been shown, it is not a state or federal regulatory requirement at the proposed site. Based upon the engineering procedures performed particular to this proposed site, it is not necessary.

Paragraph 3:

JAM refers to the study conducted for the USEPA by ICF, Inc. in 1995 in which they conclude that there are a total of seven constituents found in inert landfills that are "problematic". He states that a total of 11 C&D landfills were used in the study--in actuality, they used a total of 21 C&D landfills for their study. Munter lists the following contaminants that the USEPA found to be problematic:

- iron;
- manganese;
- total dissolved solids;
- other metals (additional metals on the USEPA list were cadmium and lead);
- organic compounds (organic compounds on the USEPA list were 2,2-Dichloroethane and Methylene chloride).

Munter also included the following constituents as being considered problematic by the EPA, but they actually were not included in the EPA's list of problematic contaminants:

- sulfate (this was not on the USEPA list);

- arsenic (not on the USEPA list);

Clearly, JAM did not read the USEPA document carefully.

It should also be noted that iron, manganese, and other metals that have been found to be problematic are typical to appliances and other metals that, in the past, and at other sites, have been buried. The proposed monofill is taking in post recycling waste; this waste has been processed to remove metals, appliances, etc. for their commodity value. It would, therefore, be reasonable to expect much lower concentrations of these materials in the inert materials to be deposited in the proposed monofill.

Paragraph 4:

JAM refers to the study by the state of Ohio EPA (June 12, 2009). He points out that in their study they found some inert landfill leachates that contained contaminants that would violate Ohio discharge limits to groundwater and surface water from organic compounds, metals, and inorganic compounds. They state that their study indicates that both municipal solid waste (MSW) and inert waste (C&DD) may produce leachates that are a threat to human health.

The Ohio EPA goes on to state that the degree of risk associated with the threat from a release of either type of leachate is dependent upon:

How the material in the landfill was disposed-

It is not clear precisely what this means, but M&A takes it to mean the nature of the materials disposed in the monofill. As stated in the Operations Plan for the proposed monofill (and on page 6 of the M&A report dated December 13, 2013), the product to be disposed is the by-product of the CRS recycling facility in Anchorage, Alaska. The material brought to the CRS will be both manually and mechanically sorted, screened, and processed through to ensure that the material is free of hazardous material, and putrescible material and/or liquids. The materials will be shredded and these inert products will be placed in a trailer and hauled to the monofill in Palmer. Thus, every effort is made to ensure that no materials that may produce a harmful leachate will be present in the monofill.

The location of the landfill-

The proposed monofill will be located in an area of relatively low precipitation, with the base of the refuse a minimum of 10-feet above the seasonal high water table.

Site conditions-

The monofill will be located in a semi-arid environment, where the annual precipitation and annual evaporation are essentially equal. Under these climatic conditions,

particularly when precipitation is less than 15.75-inches per year (described later in this document), leachate is not formed in a landfill.

Operations-

The operational procedures are described, in detail, in the Operations Plan contained in the CUP application, but the following is a general summary of the way the monofill will be operated:

The inert material will be placed to fill the natural and manmade dry voids of the property and take advantage of all the onsite features such as existing material berms and valleys.

Before any waste material is placed in the monofill, the bottom layer of the cells will be established using groundwater information. The bottom cell will be located a minimum of 10 feet above the established seasonal high-water levels.

A total of 10 main cells main will be constructed over the life of the monofill; the cells will be identified as A through I. The first cell to be constructed will be Cell A or B, with the rest of the cells being constructed in the order which best facilitates progress of the filling operations.

After each cell lift is filled completely, a bulldozer will spread 6"-12" of excess soil, strippings, and non-organic overburden on top of the cell's inert debris, creating a fire barrier.

As the top sections of the monofill are completed to final height, 24-inches of native or imported soil will be spread over the top to serve as a final cap and to allow the re-establishment of vegetation on the site within a reasonable period of time.

Slopes will be established as the monofill is constructed to maintain structural stability of the filled materials and to establish the necessary surface drainage to divert as much surface water as possible off of the monofill surface and thus minimize the amount of potential infiltration of water into the inert debris. The slopes will be 2:1 at their steepest when reinforced with tire bales, and 3:1 or less everywhere else. These are slopes of significant grade:

- 2:1 = 50% grade
- 3:1 = 33% grade

Where present, such grades will greatly facilitate the flow of water from the monofill surface, thus significantly reducing the amount of infiltration into the refuse.

Alaska State requirements are met for inert landfill with respect to the following:

- Minimum separation from water table of 10 feet
- No liner required

Leachate Management-

As described, in detail, in a later section of this document, based upon the location and climatic conditions in the area of the proposed monofill, the formation of leachate is unlikely and not anticipated. Therefore, it is doubtful that leachate management will be required.

Closure-

The landfill will be closed per ADEC regulations. Their closure regulations are more than adequate to insure successful closure.

Post Closure Care-

The CUP application discusses, in detail, the more than adequate post closure care that will be provided for the monofill.

Circumstances surrounding the site, which often change over time-

The procedures that will be followed during landfilling operations and those to be followed after site closure are described in the CUP application.

***EXAMPLE OF A STUDY OF LEACHATE PRODUCED BY LAND-DISPOSED RESIDENTIAL WASTE**

The Journal of Environmental Engineering (2002) conducted a study of the nature of leachate produced from residential construction waste. The procedure and results were as follows:

Four test-cells were excavated, lined, and filled with solid waste from C&D activities. Leachate samples were collected and analyzed for a number of water quality parameters over a 6-month period. No volatile or semi-volatile organic compounds were detected at elevated constituent levels in the leachate. Inorganic ions were found to account for the bulk of the pollutant mass leached. Calcium and sulfate were the predominant ions in the leachate, resulting from the dissolution of gypsum drywall. The concentrations of several leachate constituents were found to exceed water quality standards. These constituents included aluminum, arsenic, calcium, manganese, iron, sulfate, and TDS. Arsenic was the only primary MCL exceeded. The arsenic was concluded to be from chromated copper arsenate (CCA) treated wood. The potential risk of impacting groundwater was examined by comparing the measured constituent concentrations with the water quality standards to assess the amount of dilution and attenuation needed in the groundwater so that water quality standards would not be exceeded. The water quality standards exceed by the greatest magnitude as manganese, followed by iron.

It is apparent that unless C&D materials are not screened carefully, as was apparently the case in the Ohio EPA study, typical C&D materials GENERALLY do not produce

harmful leachates. The arsenic detected, was in this test, from treated wood that was not excluded from the test inert refuse.

PARAGRAPH 5

JAM states that many of the wastes proposed for the monofill, including wood, drywall, carpet, and probably tire bales are not geologically stable in the Palmer area; waste breakdown will inevitably result in dissolution and entrainment of waste constituents in leachate if water flows through the waste.

As stated above, leachate is not likely to be generated in the monofill. The lack of the large volumes of percolating water which, if present, would accomplish JAM's envisioned dissolution and entrainment of waste constituents, is described in our response to his critique of Section 7.2, pages 17-20 contained later in this document.

PARAGRAPHS 6 THROUGH 10

JAM repeatedly comes back to his assertion that the inert waste contained in the proposed monofill will be infiltrated by LARGE VOLUMES of precipitation, thus leaching large amounts of hazardous materials from the INERT waste. Please refer to a later section in this document, SECTION 7.2 PAGES 17-20 for a refutation of this contention. JAM's assertions are not supported by the evaluation/analyses performed.

PAGE 5 PARAGRAPH 2

ADEC regulations for inert landfills require a minimum distance of 10-feet between the bottom of the refuse and the recorded historic high water table. The on-site groundwater monitoring wells were installed in April 2013. The initial water levels were measured on 4/24/13, with the most recent round of measurements conducted on 1/23/14. It is a fact that there are not multiple years of data available to determine the historical high groundwater elevations within the subject site, but nine months of data have been collected to date. It is significant that, for the three wells that lie under the footprint of the proposed monofill (MW#2--MW#4), which can be utilized to indicate the depth to water beneath the refuse, the minimum depth to water of 25.99 feet was recorded in well MW#4 (1/23/14). The greatest depth to water recorded occurred on April30, 2013 in MW#3 (37.61 feet).

It is also significant to note that higher than normal precipitation occurred in the years 2011, 2012 and 2013 (**Appendix A**). Based upon this fact, it is reasonable to rely on the historical recorded site groundwater levels to determine historical high groundwater levels beneath the proposed monofill site.

PAGE 5 PARAGRAPH 3

JAM states that even though Secondary MCLs are only suggested levels and are not enforceable, this fact is misleading. He cites, as an example, the compound sulfate and

its possible effects on local residents and, particularly on their visitors whom may be negatively affected by excess sulfate in drinking water supplied by their hosts.

The levels of sulfate detected in the three samples of shredded typical inert materials that were subject to leaching ranged from 520 mg/L to 673 mg/L. JAM states that, at levels above 600 mg/L, sulfate in drinking water will cause laxative effects and impart a noticeable taste to the water. It should be noted that the SPLP leaching method used by SGS Laboratories to perform the leaching tests on the shredded monofill materials utilized the addition of a measured volume of a solution of acetic acid and water which, of necessity, was held in contact with the inert refuse materials for a specified period of time to attempt to leach out any soluble constituents. These concentrations will never be produced under the natural conditions that are present in the subsurface landfill environment for the following reasons:

- Acidic conditions similar to those prepared in the solutions used in the SPLP leaching procedure will not be present in the monofill environment;
- Based upon the lack of available percolating water due to the equality of the precipitation/evaporation balance, the inert refuse will not be subjected to saturation and, thus, significant leaching.
- No liner will be present at the bottom of the refuse to impede and pond any liquids that, by chance, may pass through the refuse.

The World Health Organization (WHO) published a background document in 2004 for development of WHO "Guidelines for Drinking Water Quality". They stated that cathartic effects are commonly reported by people consuming drinking-water containing sulfate concentrations exceeding 600 mg/L. The also stated that it is reported that humans can adapt to higher concentrations with time (USEPA, 1985).

The WHO document reports that there are sub-populations that may be more sensitive to the cathartic effects of exposure to high concentrations of sulfate. Children, transients, and the elderly are such populations because of the potentially high risk of dehydration from diarrhea that may be produced by high levels of sulfate in drinking water (USEPA, 1999 a,b).

In a field study that was carried out to examine the risks for diarrhea in infants exposed to tap water containing sulfate with a median concentration of 264 mg/L and a range up to 2,787 mg/L, compared with the risks for those not using tap water or using low-sulfate tap water, there was no significant association between sulfate ingestion and the incidence of diarrhea for the range of concentrations studied (USEPA, 1998 a).

The WHO stated that review of the literature and a study to experimentally determine a sulfate dose that would induce effects in adults concluded that it was not possible to set a health-based standard for sulfate in drinking water and this confirmed the conclusions of other workers such as Backer (2000) and Backer, et. al. (2001). They concluded that existing data do not identify a level of sulfate in drinking water that is likely to cause adverse human health effects.

Mr. Dan Young has conducted vadose zone modeling to predict the likelihood of increased concentrations of sulfate entering the groundwater beneath the proposed monofill. His conclusions were that there will be no significant increase in sulfate concentrations entering the groundwater and none beyond the monofill boundaries. His modeling result will be submitted separately.

PAGE 5 PARAGRAPH 5

JAM again states that M&A's conclusion that "it is not likely that a significant volume of liquids will pass through the monofill bottom into the water table" is not considered reliable. This position is refuted in M&A's response to JAM's critique of Section 7.2, pages 17-20 of M&A's December 13, 2013 report, contained later in the present response document. Briefly, the Palmer site is located in a semi-arid climate, with an annual volume of precipitation that is essentially matched by the annual volume of evaporation. Numerous investigators (references contained at the end of this document) have studied the production of leachate in landfills located in semi-arid climates and have concluded, that, generally, when the annual precipitation is less than 15.75-inches no leachate is produced--some authors use the figure of approximately 19-inches as the cutoff value. The average annual precipitation rate measured at the Matanuska AES (since 1917) indicates that the annul precipitation in the area of the proposed monofill is approximately 15-inches.

PAGE 5 PARAGRAPH 6

JAM stated that he did not find any evidence that groundwater modeling results were used to determine the proper location of "guard wells" downgradient of the monofill. One year of groundwater monitoring will be conducted in the existing on-site wells in order to collect sufficient data to determine if it will be necessary to construct down gradient guard wells.

The groundwater monitoring wells that have been constructed at the site were installed to:

- Determine the depth to groundwater beneath the base of the refuse in the proposed monofill in order to meet the ADEC requirement to maintain a 10-foot buffer zone between the refuse and the water table;
- Collect data for modeling.

Modeling results have indicated that there will be no contaminant plume extending down gradient from the landfill mass. Therefore, it is not expected that additional down gradient wells will be required.

PAGE 6 PARAGRAPH 1

JAM's comments are not valid. The Site Conceptual Model section in the M&A report dated December 13, 2013 contains data pertinent to the conclusions developed following an extensive evaluation of conditions at the site and adjacent areas. Those conclusions indicated that, as the result of the relative precipitation/evaporation balance, no leachate would be produced. As such, there are no pathways that are likely to impact human health.

PAGE 7 PARAGRAPH 2

Landfill regulations do not typically list the large numbers of materials that are allowed, but just those that are prohibited. If, at some future time, the ADEC lists additional materials that are prohibited, or limits materials that are allowed, the CMS acceptance criteria will be modified accordingly.

PAGE 7 PARAGRAPH 4

Others will respond to JAM's critique.

PAGE 7 PARAGRAPH 9

JAM's critique appears to state that the grade of the final monofill cap of 2% to 3%, which is certainly not a steep surface, and will be conducive to groundwater recharge and downward percolation of precipitation through the refuse. This is a simple concept and incorrect.

It is incorrect particularly at landfills located in a semi-arid climate. In *"Guidance Note on Leachate Management for Municipal Solid Waste Landfills"*, by The International Bank for Reconstruction and Development/World Bank (1999), the amount of leachate produced in semi-arid climates and the geometry and progressive evolution of a landfill during filling is described.

The World Bank publication evaluates the potential for production of leachate as follows:

Leachate is generated primarily from precipitation and thus is principally influenced by climatic conditions such as rain and respiration. In arid climates, virtually no excess leachate occurs; in semi-arid areas, leachate may be generated irregularly or only at certain times of the year. For arid and semi-arid areas, the quantity of leachate generated may be insignificant and may have no unacceptable impact on the environment; therefore, leachate management may be limited.

Also, the quantity of leachate generated varies significantly from open cells to closed cells. Therefore, the evolution of leachate quantity throughout the lifetime (i.e., from the first cell to the final cover of the entire disposal area) of the landfill should be reflected in leachate quantity estimates.

As cells are completed and there is no working face, infiltration will decrease significantly. So, as each cell is completed, and the vegetative cover established, the volume of infiltration will be significantly reduced. As vegetative cover is added, most precipitation will evaporate. On page 20, it states, "A final top cover may be used to control the volume of leachate generated. A simple top cover with vegetation will reduce infiltration through evaporation."

As the landfill expands and more cells are completed with the final vegetative cover, the volume of infiltration will be reduced. The volume of potential infiltration will be very low to begin with, and will be further reduced as the landfill evolves, CELL BY CELL.

The conclusions of the World Bank study are applicable to the Palmer site, based upon the semi-arid climate and the mechanics of the monofill construction.

PAGE 10 PARAGRAPH 1

JAM states that, "This section does not address changes in water levels caused by gravel mining." He appears to have missed Section 6.2, on page 11, that discusses, in detail, the conclusions of his April 2010 report for the Matanuska-Susitna Borough titled "*Potential Hydrologic Effects of Gravel Extraction South of Palmer, Alaska*". In that report he concludes that gravel mining close to the proposed monofill site could have the effect of lowering the water table several feet over an extended area. The monofill site will lie within the area of projected water table decline. If JAM is correct, the lowering of the water table would aid in maintaining the 10-foot minimum separation required for the monofill by the ADEC.

PAGE 13 PARAGRAPH 5

Section 6.3 of the M&A report dated December 13, 2013 titled "Water Quality in the Ponds Located Within the Site" contains data to indicate that the relative lack of contamination in the ponds supports the fact that the site has not been contaminated by the previous industrial activities conducted at the site. The ponds are directly connected to the groundwater beneath the site, with groundwater flowing into them from the up gradient direction and out of them in the down gradient direction. They are, in effect, windows into the groundwater beneath the site. Based upon the southwesterly direction of groundwater flow, any areas of contaminated soil present in the northern 2/3 of the property should be reflected in poor water quality in the ponds.

The contents of this section of the M&A report are not critical to approval of the CUP application for the monofill construction. JAM's inclusion of this section in his critique was not critical to approval of the CUP application.

PAGE 14 PARAGRAPH 2

Please see the EMI response attached for an explanation of the SPLP testing.

PAGE 14 PARAGRAPH 3

Please see the EMI response attached for an explanation of the SPLP testing.

PAGE 15 PARAGRAPH 1

JAM's criticisms of Secondary MCLs have been previously addressed in this document; the potential effects of sulfate in drinking water have also been addressed in this response.

SECTION 7.1.1 PAGES 15-17

JAM refers to studies by the Ohio EPA, the USEPA, and the State of Wyoming, each of which were discussed in the M&A report of December 13, 2013. He particularly refers to the Ohio EPA study that states that C&D leachate is not expected to meet water quality standards for discharge to groundwater. He states that, "The take-away messages from these three studies seem to be that C&D leachate should be considered a pollutant, this pollutant should be expected from C&D landfills that generate leachate (repeat?), and that good management practices can be helpful in reducing the impact of the leachate."

The potential for the generation of leachates containing hazardous substances from inert landfills is directly dependent upon the effectiveness of the screening that is done prior to landfilling of the materials. This is one of the conclusions of the Ohio EPA report in their statement that "good management practices" are necessary to reduce the impact of leachate. Central Monofill Services has a very efficient screening process to remove all hazardous materials prior to accepting them for landfilling. This screening process is described in detail in their Operations Plan contained in their CUP application. This process was described in M&A's December 13, 2013 report. The concerted effort to screen-out all hazardous materials from the refuse accepted for landfilling reduces, to the greatest extent possible, the possibility of materials being landfilled that could produce leachate of harmful composition. However, as shown by the fact that the proposed site is located in a semi-rid climate, and the relative balance between the annual precipitation/evaporation volume, there will not be enough infiltration to produce leachate.

The position adopted by the ADEC is that, based upon all of the site factors, including material screening and the lack of leachate production in semi-arid climates (annual precipitation/annual evaporation approximately equal), the proposed monofill, in its present design, will not pose a threat to public health.

The National Demolition Association document titled *"Demolition Contractors Manage and Dispose of Waste Responsibly"* (February 1995), contains data that indicate that

many landfills that are presently labeled as "inert landfills" are actually sites that, prior to being converted to inert waste disposal sites, were municipal solid waste disposal sites. They point out that, in many instances, it is difficult for researchers to discover this fact when compiling leachate-composition data. Therefore, leachate-quality data for many inert landfills may be biased toward hazardous compositions.

Of primary importance is the fact that, as described later in this document, little or no hazardous leachate will be produced by the proposed monofill. Modeling completed by others will be submitted to substantiate this fact.

SECTION 7.2, PAGES 17-20:

- Page 17/paragraph 6: JAM states that Maddox & Associates, Inc. (M&A) incorrectly used the term rainfall to represent all of the liquid that has the potential to infiltrate into the subsurface at the proposed monofill site. In the initial sentence of paragraph 6, the term "precipitation" is used and the follow-up use of the term "rainfall" should be understood as "precipitation". M&A, being a Southern California firm, does not typically get involved with differentiating between the two terms. However, on November 26, 2013 M&A spoke to Mr. Rick Thoman, Climate Sciences & Services Manager of the National Oceanic and Atmospheric Administration (NOAA), at the NOAA National Weather Service Alaska Region Forecast Office (907-458-3716). Mr. Thoman explained that, "Precipitation is the total of rainfall plus the melted snow that hits the ground and is available for potential infiltration or runoff." Runoff of precipitation is an important factor in the reduction of infiltration. It is facilitated by such factors as composition of cover materials, compaction of materials, and slope, among others.

  M&A also called and spoke to a supervisor at the Alaska Department of Transportation and Public Facilities, Mr. Jack Stickle (907-209-0240), and asked for a definition of the term "precipitation" with regard to rainfall and snow. Mr. Stickle essentially replied as had Mr. Thoman.

  Thus, M&A, does, indeed, understand the whole meaning of "precipitation", and in every portion of the M&A report dated December 13, 2013 that was the implied meaning of the words in question.

In response to the remainder of JAM's comments pertaining to Section 7, pages 17-20, the following section contains a discussion of the potential for infiltration of precipitation at the proposed monofill site, expanded beyond that contained in the M&A report dated December 13, 2013.

POTENTIAL FOR INFILTRATION OF PRECIPITATION INTO THE SUBSURFACE AND PRODUCTION OF LEACHATE AT THE PROPOSED MONOFILL SITE:

Semi-Arid Climate and Potential for Leachate Production:

The area of the proposed monofill, near Palmer, Alaska, is located in a semi-arid climate. The climate of an area is a primary factor which determines the amount of leachate produced in a landfill or monofill.

The production of leachate in a landfill is governed by two primary factors:

- The annual precipitation;
- The amount of annual evaporation and evapotranspiration.

The net difference between annual precipitation and annual evapotranspiration is the amount of water left over, and available for possible infiltration through the refuse--this water has the potential to become leachate. This general calculation is called the water balance. When the two factors are close in value, the potential for the production of leachate is low.

The annual precipitation in the area of the proposed monofill is stated by some to be just short of 15.0 inches per year, and some values given are just over 15.0-inches per year. M&A utilized annual precipitation data from the Matanuska AES Weather Station, operated by the Alaska Climate Research Center, which determined an annual precipitation rate of 15.32-inches over the period 7/4/1917 through 12/31/2005. This is the value selected for our calculations for the proposed monofill site. The table from the Matanuska AES Weather Station is contained in **Appendix B.**

According to Green, Bertetti, and Hernandez (2012) a semi-arid climate is defined as one having an average annual precipitation of less than 50 cm/year (19.7 inches). They state that "recharge approaches zero when precipitation decreases below about 43 cm/year (16.9 inches)".

As stated above, the site of the proposed monofill, near Palmer, Alaska is located in a semi-arid climate, with an annual precipitation of approximately 15.32-inches per year.

Aljaradin and Perrson (2012) state that, "For climates where annual precipitation is less than 400 mm (15.75-inches), virtually all precipitation is evapotranspirated. In cases where no significant leachate is produced, it may be possible to relax the standards required for the design of a landfill by omitting the leachate collection system and under-liner."

Data provided by Aljaradin and Perrson indicate that in climates with an annual precipitation rate of approximately 15.0-inches per year, such as at the Palmer monofill location, the production of leachate is unlikely.

Johannessen (1999) states that, "Non-control of the potential release of leachate may be applied to inert waste landfills (i.e., for construction waste or soil) and to MSW landfills in arid climates."

In Johannessen's paper, which was prepared and published by The World Bank, he further states that in semi-arid areas, leachate may be generated irregularly or only at certain times of the year. He also states that, "For arid and semi-arid areas, the quantity of leachate generated may be insignificant and may have no unacceptable impact on the environment; therefore, leachate management may be limited."

Johannessen points out that the quantity of leachate generated varies significantly from open cells to closed cells. Therefore, the evolution of leachate quantity throughout the lifetime (i.e., from the first cell to the final cover of the entire disposal area) of the landfill should be reflected in leachate quantity estimates.

The most vulnerable portion of the monofill at any one time is the "working face" the area within a cell where active filling is taking place and heavy equipment is compacting and covering the refuse; in the instance of the proposed monofill the working face would typically cover an area of approximately 120 feet by 50 feet. As cells are completed and there is no working face, the potential for infiltration will decrease significantly. Stoller states that, "In humid regions, keeping water received as precipitation from reaching interred wastes can be a formidable problem, but in arid or semi-arid areas, a natural ecosystem analogue provides a simple and elegant solution. Because the potential to evaporate water far exceeds the amount of water received as precipitation, many arid (and semi-arid) land ecosystems return all of the water received to the atmosphere via evapotranspiration. The soil serves as a reservoir, temporarily storing precipitation that is not immediately evaporated. In turn, plants extract that water from the soil and return it to the atmosphere.

With the establishment of a vegetative cover as each cell is completed and the monofill expands, the volume of infiltration will be significantly reduced. The development of a vegetative cover will result in increased evaporation (evapotranspiration) and the minimal (to none) infiltration that may be present to begin with will be reduced to essentially nothing as the landfill evolves, cell by cell. The valley floor is naturally wooded by white spruce, birch, and aspen on the better drained and sandy soils, while the ground cover consists of ferns, currants, high-and low-brush cranberries, wild rose, horsetail, blue-top, and dwarf dogwood. Establishment of the native ground cover flora on the final cap of each cell would result in increased evaporation, and thus, reduced potential for infiltration.

EXAMPLE: The Effect of Rainfall V/S Evaporation on the production of Leachate at Three Landfills Located in Various Climates

Peirce, Weiner, and Vesilind (1997) state that the amount of leachate produced by a landfill is difficult to predict. They state that the only available method is water balance. The water entering a landfill must equal the water flowing out of the landfill--the leachate. They calculated the water balance for three landfills, located in Cincinnati, Orlando, and Los Angeles. As a result, they stated that, clearly, Los Angeles landfills may virtually never produce leachate, while the other two produced a significant amount of leachate. The following table is reproduced from page 171:

Table 13-2. Percolation in Three Landfills

Percolation Location	Precipitation P (in.)	Runoff Coefficient R	Evapotranspiration E (in.)	*Total Percolation (in.)
Cincinnati	40.35	0.15	22.36	8.39
Orlando	52.83	0.07	46.14	2.76
Los Angeles	14.88	0.12	13.15	0

*total percolation is defined by the authors as the amount of leachate produced.

It is very significant to note that, even though the annual precipitation in Orlando is approximately 24% higher than that in Cincinnati, the amount of leachate produced by the Cincinnati landfill is three times that produced in the Orlando landfill--this is due to the much greater amount of evapotranspiration that occurs in the Orlando area. The total annual precipitation in an area is not the only important factor that determines the amount of leachate produced in a landfill--evapotranspiration is of equal importance.

It is also significant that, for Los Angeles, the precipitation and the evapotranspiration are very close in value, and thus there is no production of leachate. Los Angeles is located in a semi-arid climate, with an annual precipitation value (14.88-inches) very similar to that of the Palmer area. As stated above, the annual precipitation in Palmer is approximately 15.32-inches, and so both are located in semi-arid climates. As in the case of Los Angeles, the value of the annual precipitation and evapotranspiration in Palmer are similar in magnitude:

- Palmer area annual precipitation: 15.32-inches
- Palmer area annual evapotranspiration: 13.968-inches

Case Study of a Landfill Located in a Semi-Arid Climate: Palos Verdes Landfill, Los Angeles, California:

The data presented in this section is taken from, "Remedial Investigation Report Palos Verdes Landfill, Volume I", prepared for Department of Toxic substances Control Cal/EPA by Sanitation Districts of Los Angeles County, June 1995.

The Palos Verdes Landfill (PVLF)is located in the south-central portion of Los Angeles County, on the Palos Verdes Peninsula. The total landfilled area is 173-acres.

Site History:

The landfill is located at the site of old mining and quarrying operations. The materials mined were sand and gravel and diatomaceous earth. Landfilling operations were conducted from May 1957 through December 1980. The landfill was closed in 1981.

Groundwater Contaminant Transport Modeling:

The objective of the groundwater contaminant transport modeling, described in Appendix E.1.3 of the report, was to develop an analytical tool based on the geologic conditions around the PVLF such that the current and future concentrations of chemicals in groundwater could be reasonably estimated and then used for a baseline health risk assessment. To provide technical support for the risk assessment, hydrogeologic modeling was conducted to simulate the groundwater flow, and contaminant transport modeling was conducted to simulate movement of chemicals between the landfill and potential receptors and to estimate concentrations of chemicals in groundwater at those points.

Because of the complex geologic conditions at the PVLF, simplifying assumptions were necessary to facilitate mathematical solutions of the transport equations. The assumptions made in the development of the groundwater transport model, however, were designed to result in the development of modeled chemicals such that the model could be used to evaluate health risks associated with the groundwater transport pathway based on the maximum expected concentrations. For example, the actual field groundwater monitoring data (discussed in section 3.6 of the report) did not detect any leachate formation and release from the PVLF. But the contaminant transport model constructed assumed continuous release of all modeled water quality parameters and used the information as an initial condition for long term predictive analysis. The purpose of the unrealistic assumption was to investigate the health risk associated with the worst case scenario of groundwater contamination.

The program used to conduct the modeling as called "Hydrologic Evaluation of Landfill Performance (HELP)". The following table from Appendix E.1.3 contains the average monthly precipitation at the landfill over the period 1939--1990:

Table E.1.2 (1939–1990)

Month	Average Precipitation (inches)
January	3.30
February	2.94
March	2.24
April	1.12
May	0.16
June	0.03
July	0.00
August	0.08
September	0.22
October	0.40
November	1.91
December	2.28
Total	14.68

The results of the groundwater modeling are shown in the following table:

HELP MODELING RESULTS

LOCATION	[1]TOP DECK	[2]TOP DECK
Percolation (in.)/Percent of precipitation	0.0004/0.00	0.001/0.01

[1]Sandy clay

[2]Silty clay

As can be seen, the amount of predicted leachate, expressed as a percentage of the total percolation ranges from 0.0004-inch to 0.001-inch, essentially zero. As the physical field investigation, which consisted of over 50 monitoring wells, indicated, no leachate was detected to have been produced in the Palos Verdes Landfill. It is apparent that this landfill does not produce leachate in real-life, nor is any leachate production predicted in a very conservative model. The primary controlling factors are:

- Relatively low annual precipitation;
- Annual evapotranspiration that is essentially equal to the annual precipitation.

Both of these primary factors are typical of a semi-arid climate.

Comparison of Moisture Content of Refuse in Landfills Located in Semi-Arid Climates V/S Landfills Located in Areas of Relatively High Annual Precipitation:

M&A has drilled and installed landfill gas (LFG) extraction wells in landfills located over most of the United states and in Canada. Steve Maddox was the geologist who logged each of these borings. The observed moisture content of the refuse encountered was significantly lower in areas with a semi-arid climate, such as Southern California, than that in refuse encountered within areas of high annual precipitation, such as the Mid-West, Northeast, and the Gulf Coast. A few examples follow:

Semi-Arid Locations:

- Mountaingate Landfill--Located in the foothills above UCLA (Los Angeles, CA), the refuse observed during methane gas extraction well drilling was slightly damp, to damp. Very little decomposition of the cellulose materials was observed.
- Olinda Landfill--This landfill is located in Orange County (just east of Los Angeles), in the Puente Hills. The refuse encountered in the LFG extraction wells during drilling was damp to slightly moist, with little decomposition noted.
- Operating Industries Landfill--Located in Monterey Park, immediately east of the metropolitan area of Los Angeles; during drilling this landfill produced damp refuse showing little decomposition until the bottom of the refuse was reached at 300+ feet, where some liquids had perched on an underlying siltstone stratum.
- Penrose Landfill--The Penrose Landfill is located in the San Fernando Valley, of the greater Los Angeles area. The refuse encountered in this landfill was, typically, damp and showed little decomposition.
- Southside Landfill--The Southside Landfill is located in Spokane, Washington, in a semi-arid climate with 16.5 inches of annual precipitation. The refuse encountered during drilling LFG wells in this landfill was typical for a semi-arid area--it was only slightly damp and showed only moderate decomposition.

Summary: In our experience, the landfills located in semi-arid areas exhibited only slight moisture content and the level of decomposition was slight. This was true even for the landfill located at a fairly high latitude, in Spokane, Washington.

Areas of Relatively High Annual Precipitation:

- 31st Street Landfill, Chicago, Ill. (37 inches annual precipitation)--The refuse encountered during LFG well installation was "sloppy" wet, and showed significant decomposition.
- Holloway Landfill, Detroit, Michigan (32 inches annual precipitation)--The Holloway Landfill refuse was wet and significantly decomposed.
- Miron Company Landfill, Montreal, Canada (40 inches of annual precipitation)--The Miron Company Landfill exhibited refuse that was significantly wet and in a state of advanced decomposition.

- McCarty Road Landfill, Houston, Texas (50 inches precipitation annually)--As with the other landfills located in climates with a high level of annual precipitation, the McCarty Road Landfill refuse was wet and decomposed.

Summary: Experience drilling in landfills located in areas of relatively high annual precipitation indicates that the refuse, particularly those materials composed of cellulose, are typically very moist to wet and in an advanced stage of decomposition.

Winds-A Major Factor in the Occurrence of Evaporation in the Matanuska Valley--a Semi-Arid Area:

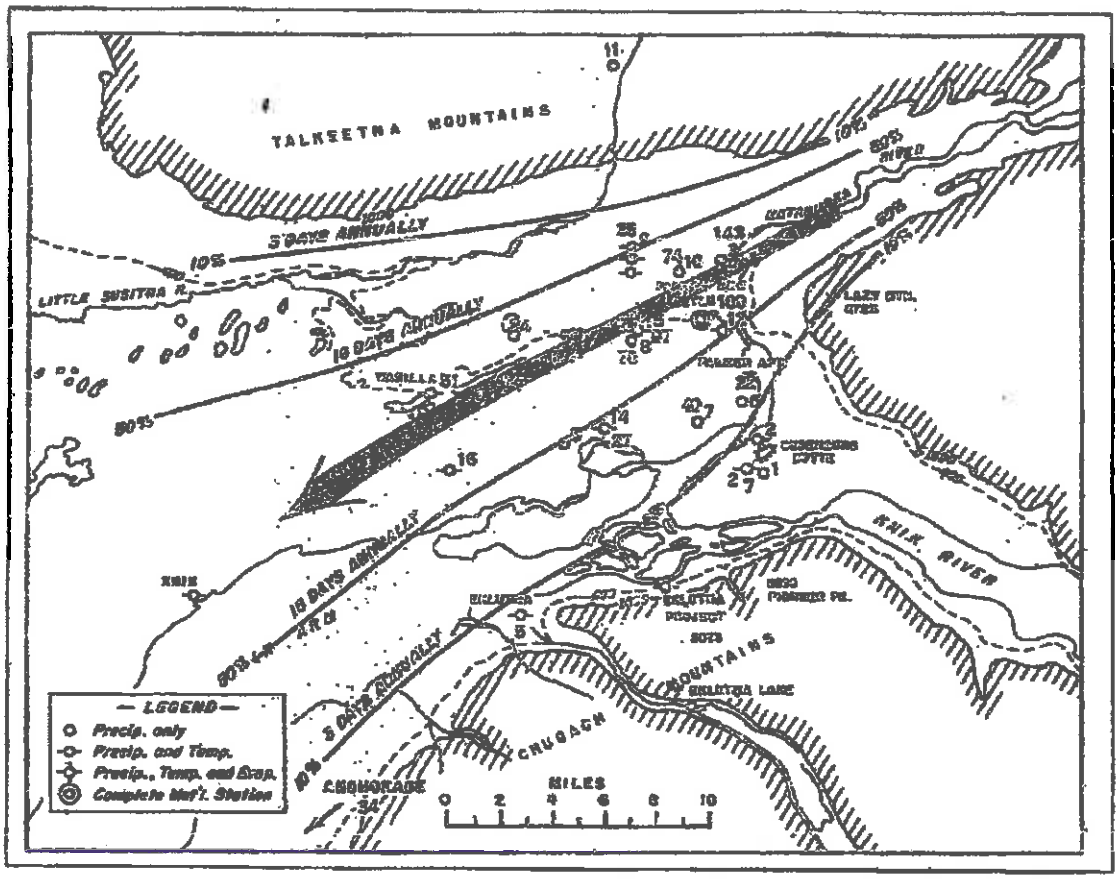
Much of the data contained in this section are derived from *"The Climate of the Matanuska Valley"*, U.S. Department of Commerce, Weather Bureau, Technical Paper No. 27, March 1956. The study is based primarily on about 34 years of record from the Matanuska Agricultural Experiment Station (Matanuska AES) and also an average of more than 11 years of record for Matanuska No. 2, No. 9, No. 12, , No. 15, Wasilla (No. 13), and Eklutna (established at the Anchorage Hydroelectric Power Plant in May 1941). The Matanuska AES is located approximately 2.5 miles to the west of the proposed monofill site.

Due to its unique location and surrounding topography, the Matanuska Valley is the site of winds that are particular to it. The Chugach Mountains to the south and east, with peaks ranging from 7,000 to 10,000 feet, form an effective barrier to all flow of moist Pacific air except from the southwest over Cook Inlet. The Alaska Range and the Talkeetna Mountains to the north prevent the flow of air masses from the north. The surrounding mountains and the topography of the valley floor serve to channel the local valley winds: the persistent, cold, gusty, northeasterly "Matanuska Winds", and the warm, generally ephemeral, southeasterly "Knik Winds". Each of these winds remove a significant amount of moisture from the valley surface by evaporation.

Both the Matanuska Winds and the Knik Winds are caused by a strong pressure gradient when the gradient becomes properly aligned with the respective river valleys.

Matanuska Winds:

The Matanuska Wind path extends west-southwest over the lake chain into the Wasilla area. As shown in Figure 1 (Figure 18 from Technical Paper 27), the axis of the wind path comes out of the canyon of the Matanuska River and flows in a southwesterly direction through Palmer and Wasilla, and on toward Anchorage. Although the heavy arrow shows the axis or the most frequent path of the Matanuska wind, the wind does not always follow the same channel but varies somewhat with the direction of the gradient. These winds facilitate a significant amount of evaporation of moisture from the Matanuska Valley, particularly in the area of the proposed monofill (near Station 14, Matanuska AES). Trainer (1960) states that it is an autumn and winter wind and



TAKEN FROM: "THE CLIMATE OF THE MATANUSKA VALLEY", TECHNICAL PAPER 27, U.S. DEPARTMENT OF COMMERCE, WEATHER BUREAU, MARCH 1956

MADDOX & ASSOCIATES, INC. 39371 SAN THOMAS CT. MURRIETA, CA 92562 (951) 605-1100	MATANUSKA - SUSITNA VALLEY ALASKA	FIGURE 1 PERCENTAGE OF NUMBER OF DAYS OF MATNUSKA WINDS REPORTED AT NO.12 AND MATANUSKA WIND PATH	DATE: 04/09/14 SCALE: AS SHOWN REVISED:

sometimes blows almost continuously for several days or longer. Weather Bureau records indicate gusts reaching 50 miles per hour during the more severe storms.

Knik Winds:

Figure 2 (Figure 23 of Technical Paper 27) shows the approximate path of the Knik Wind. The most frequent path of the Knik Wind is down the Knik River with the width of the wind path limited primarily to the width of the river bed. This most frequent occurrence of the Knik Wind is evidenced by clouds of dust on the lower Knik River flats (Figures 3 and 3A), but causes little damage and is generally felt only at the Knik River bridge and a few farms immediately adjacent to the river in the vicinity of the bridge; it requires little gradient and is generally spent by the time it reaches Knik Arm. As can be seen in Figure 2, this wind does not typically flow far out into, and through, the Matanuska Valley as does the Matanuska Wind, but there is still a strong flow by the time it reaches the area of the proposed monofill. As occurs with the Matanuska Winds, the Knik Winds remove, by evaporation, a significant amount of moisture from the area of the monofill (near the Matanuska AES).

Effect of Winds on Evaporation in the Matanuska Valley

Correlation of average monthly evaporation and wind movement in the Matanuska Valley is shown in Table A (Table 8 of Technical Paper 27):

Table A
Average Monthly Evaporation and Wind Movement at Matanuska AES, 1929-1952

EVAPORATION & WIND VALUES	MAY	JUNE	JULY	AUGUST	SEPTEMBER	OCTOBER
AVERAGE EVAPORATION (IN.)	4.86	4.29	4.17	2.91	1.78	0.92
Average length of record (yrs.)	1	10	13	18	12	2
AVERAGE WIND SPEED (MPH)	4.3	3.5	2.7	2.4	3.0	4.2
Average length of record (yrs.)	5	14	13	18	14	7

Only months for which complete evaporation data were available were used to compile this table. For the many years over the period covered by this table, ice forming in the evaporation pan prevented complete evaporation measurements during the seasons when freezing occurred. This is reflected by the fact that the soils in the area of the Matanuska AES are usually frozen from October and into April/May (Appendix D), as would be the water in the evaporation pan. Consequently, the average length of record for the months

of May and October were only 1 to 2 years, and, typically, no evaporation data were measured from November through April. On the other hand, evaporation data were available for long periods of years for the months during which the soils were not frozen.

As can be seen, the highest evaporation rates occurred during the months when the average wind speed was highest. Exceptions were during September and October, but the soils were typically frozen or near-frozen during those months, thus reducing the rate of evaporation. It should be noted that, even though the evaporation pan can't be used to reliably calculate the amount of evaporation that occurs when the soil is frozen, and therefore no measured data are available, the process of evaporation continues, albeit at a reduced rate, during the winter months.

It is apparent that winds are a major factor in the balance between precipitation and evaporation that determines whether, or how much, leachate is produced in a landfill. The winds in the semi-arid Matanuska Valley, both the Matanuska Wind and the Knik Wind, are a major factor in reducing the amount of precipitation that is available to infiltrate into the proposed monofill. The addition of regular, systematic winds to an area with a semi-arid climate such as is present in the Matanuska Valley further reduces the likelihood of leachate production in a landfill. Trainer (1960) states that the Knik Wind is relatively warm, and in the late winter and spring it brings mild weather and in many years it removes much of the snow cover from the area before the ground begins to thaw. The net effect of this is to remove snow that, if it melted in place, would be available to infiltrate into the subsurface, thus further reducing the amount of precipitation in the ratio of precipitation versus evaporation that determines the potential for leachate production.

It is apparent that JAM is overstating the potential volume of precipitation that is available for infiltration into the planned monofill, considering the local climate at its proposed location.

Specific Factors Affecting the Potential for the Production of Leachate at the Palmer Monofill Site:

The potential for the production of leachate at the Palmer monofill site is low. This is based upon the following facts:

- The proposed monofill site is located in a semi-arid climate:

  As noted above, the relatively low annual precipitation is less than that which is indicative of a semi-arid climate (≤19.7-inches). Leachate production is uncommon in semi-arid climates.

- The annual precipitation is relatively low:

  The annual precipitation is approximately 15.32-inches and, according to Aljaradin and Perrson, most all precipitation is lost to evaporation below a value of approximately 15.75-inches.

- The annual evapotranspiration is approximately equal to the annual precipitation:

  Please see **Appendix C** for evapotranspiration data collected by the weather station designated Matanuska AES, operated by the Alaska Climate Research Center. This station is located approximately 2.5-miles to the west of the proposed monofill site, just north of the intersection of Parks Highway and Glenn Highway.

  Reference to the data contained in **Appendix C** will indicate that, over the period from 1917 through 2005, the annual rate of evaporation was 17.46-inches. Although this value exceeds the amount of annual precipitation during the same period, the actual amount of evaporation is slightly less. The data sheet contained in **Appendix C** contains the following discussion of the values measured:

  "Standard daily pan evaporation is measured using the four-foot diameter Class A evaporation pan. The pan water level reading is adjusted when precipitation is measured to obtain the actual evaporation. Most Class A pans are installed above ground, allowing effects such as radiation on the side walls and heat exchanges with the pan material. These effects tend to increase the evaporation totals. The amounts can then be adjusted by multiplying the totals by 0.70 or 0.80 to more closely estimate the evaporation from naturally existing surfaces such as a shallow lake, wet soil, or other moist natural surfaces."

  Based upon the fact that the location is in a semi-arid zone, and published data state that "For climates where annual precipitation is less than 400 mm (15.75-inches), virtually all precipitation is evapotranspirated.", a factor of 0.80 was used and the corrected annual evaporation was calculated to be approximately 14.0-inches.

  Additionally, data obtained from the Matanuska AES over a recent 30-year period (1982-2012) indicate a total precipitation of 15.9-inches and a corrected evaporation of 14.7, a slightly smaller delta than for the period 1917-2005. These data are contained in **Appendix A.**

  Many stations do not measure pan evaporation during winter months. A "0.00" indicates no measurement is taken." Reference to the evaporation data sheet contained in **Appendix C** will indicate that no measurements are taken from October through April--during this period the ground is frozen. It is possible that, were evaporation measurements to be taken during this seven-month period, the total evaporation would be even greater. Sublimation data are not available, but moisture is lost from snow and ice during winter months by this process.

  A major contributing factor to the relatively high evaporation rate in the area of the proposed monofill are the winds that are native to the area. These winds, the

Matanuska Wind and the Knik Wind, when blowing, have been shown to result in increased evaporation from both the soils and the flora.

- The ground is frozen during a significant portion of the year:

Data from the Matanuska AES and the National Climatic Data Center, NOAA Satellite and Information Service are contained in **Appendix D.** These data indicate that there is a 90% chance that the soil in the Palmer area is frozen from approximately September 30 through May 30 of each year.

Discussions with professionals in the Palmer area indicate the following:

The soil temperatures can reach 32 degrees F. or colder. The Palmer soils tend to be coarse-grained. When the clasts are below 32 degrees F. the soil voids are unsaturated, thus somewhat permeable. As snow melts (middle winter and in the spring), water percolates downward and refreezes. This process creates impermeable soils. During spring melt, runoff can exceed 5 to 10-yer storm events, because the soil is nearly impermeable until it thaws. Thus, very little infiltration occurs during the long period during which the soils are frozen.

Reference to the average precipitation rates for an average year in the Palmer area indicates that a total of approximately 8.51-inches of precipitation occurs during the period that the soils are frozen--this represents approximately one-half of the annual precipitation.

It is apparent that with the volume of precipitation that is lost for potential infiltration due to yearly frozen soil conditions, the amount of evaporation greatly exceeds the volume of water that is available for infiltration, and thus impedes the production of leachate.

- No significant period of residency of liquids within monofill materials:

The majority of the soils underlying the proposed monofill are composed of glacial outwash sands and gravels. The hydraulic conductivity of these materials is fairly high, and they conduct liquids readily. A percolation test was conducted on July 1, 2013 and the results indicated soil permeabilities (hydraulic conductivity) in the footprint of the proposed monofill ranging from 6.0×10^{-3} cm/sec (clean sand) to 5.2×10^{-4} cm/sec (silty sand). These sediments allow for the rapid transmission of percolating water (See **Appendix E** for percolation test report).

Percolation testing of residual materials at the Birchwood Monofill, Chugiak, Alaska indicated an average hydraulic conductivity of approximately 2.0×10^{-2} cm/sec (**Appendix F**). The monofill materials are typical of those that will be deposited at the Palmer monofill. Any water that may penetrate through the proposed final cap ($K \sim 1.1 \times 10^{-4}$ cm/sec) will encounter the significant increase in

hydraulic conductivity of the monofill materials (a hundred-fold increase), resulting in a significant increase in travel velocity by the water. This increased velocity will allow infiltration without saturation. As a result, the water will pass rapidly down through the inert refuse material.

It is also possible that, with the establishment of a plant community on the monofill cap, the plant roots will be restricted to the less permeable and more moist cap soils, and evapotranspiration will remove the water before it can reach the more permeable inert materials. The mechanics of this process are outlined in the "intrusion barrier" concept described in the report by Stoller-Eser for the U.S. Department of Energy (2000).

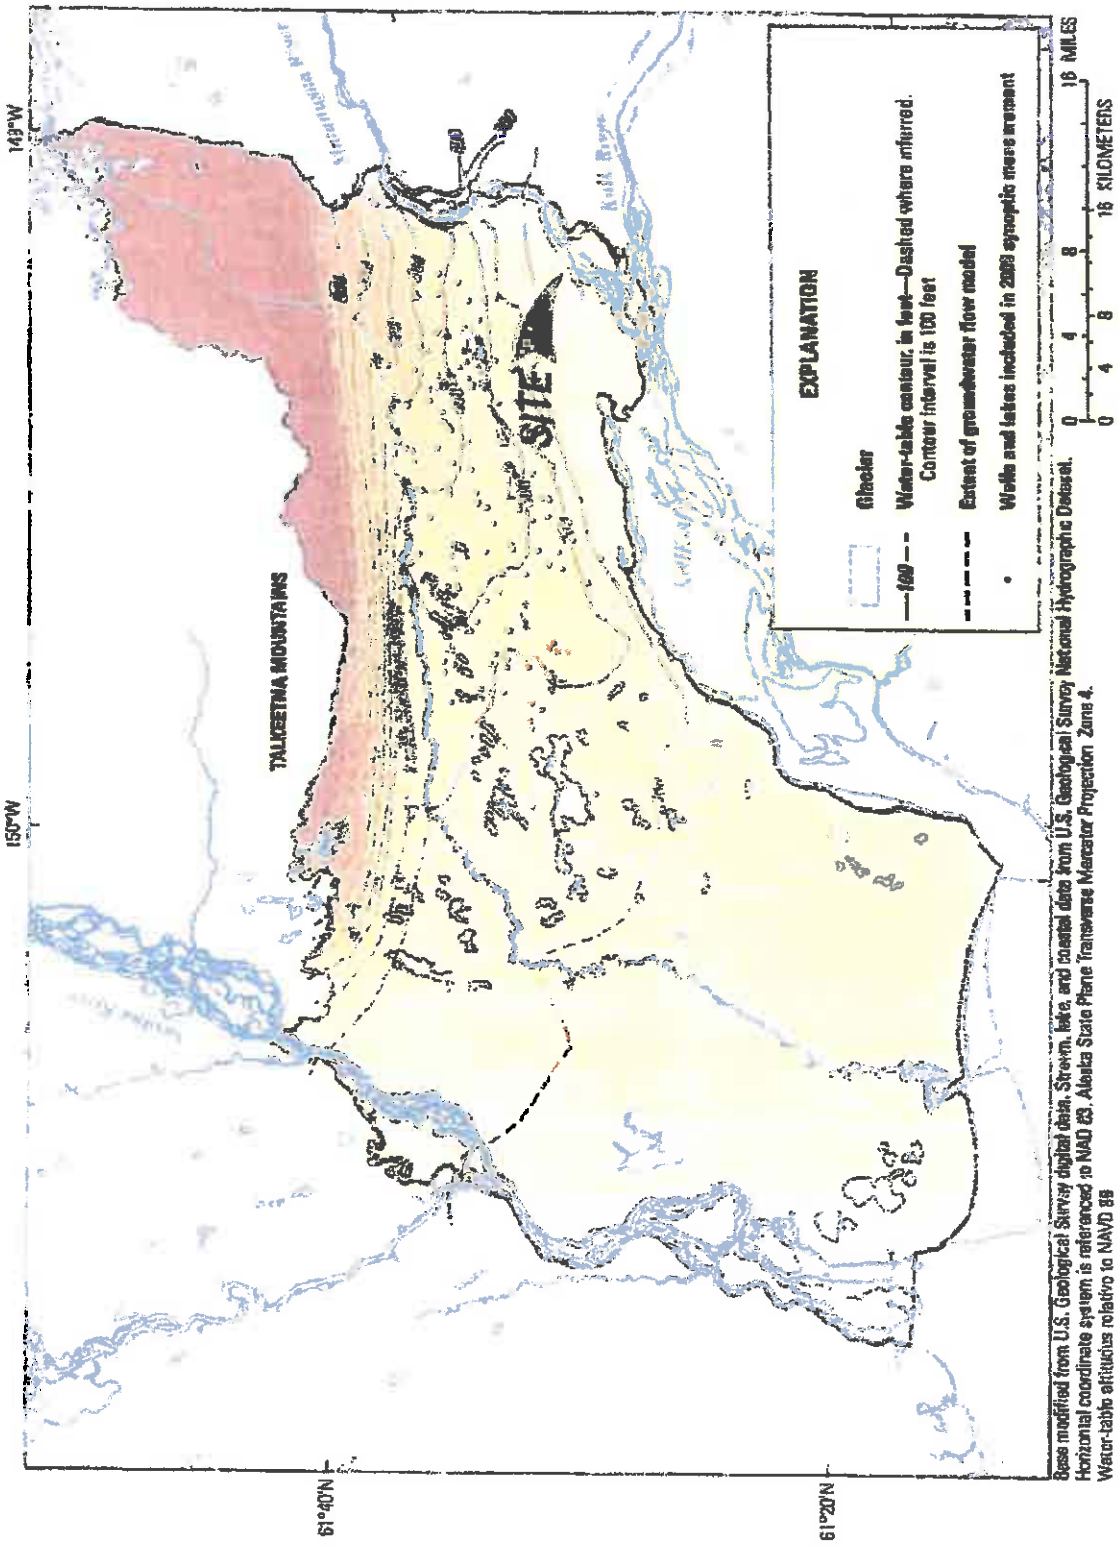
Due to the fact that the monofill will not have an under-liner, if any liquids did reach the bottom of the inert refuse, they would pass, essentially unimpeded, into the underlying natural soils. Any such liquid would, as described above, have had no residence time during which it could pond at the bottom of the landfilled materials. Thus, there would be no prolonged period of time during which the liquids would remain in contact with the inert refuse prior to passing on through the monofill bottom and into the underlying natural materials. This lack of ponding-time would result in the extraction of the minimum amount of constituents from the inert refuse.

- <u>No significant recharge in area of monofill:</u>

  JAM's position is that significant recharge of the aquifer occurs in the area of the proposed monofill. This is not true for the following reasons:

  -The precipitation that would be available to recharge the aquifer is greatly reduced by the significant evaporation that occurs and, at most, would amount to very little.

  -Kikuchi (2013) indicates that flow through the groundwater system is driven primarily by RECHARGE in the Little Susitna River Valley, located approximately 20-miles to the north of the Palmer area, following generally north to south flowpaths in the area surrounding Wasilla and transitioning to northeast to southwest flow paths in the area of Big Lake. Groundwater flow in the site area is primarily to the south and west, from the foothills of the Talkeetna Mountains, to discharge along the Matanuska River and its contributing sloughs and tributaries (Figure 4). Kikuchi (2013) states, on page 1, that, "Water moves quickly through the groundwater system. The groundwater system quickly returns to long-term average conditions following variability due to seasonal or interannual changes in precipitation." This is primarily in reference to precipitation changes in the RECHARGE area (which is not located in the Palmer area), by definition. Reference to Figure 4 will show the dense network of tributary streams flowing down from the southerly foothills of the Talkeetna Mountains, and into the Little Susitna River, whose headwaters are the result of



MADDOX & ASSOCIATES, INC. 39371 SAN THOMAS CT. MURRIETA, CA 92562 (951) 805-1100	MATANUSKA - SUSITNA VALLEY ALASKA	FIGURE 4 UPDATED WATER-TABLE CONTOUR MAP AND LOCATIONS OF 2009 SYNOPTIC WATER-LEVEL MEASUREMENTS	DATE: 04/09/14 SCALE: AS SHOWN REVISED:

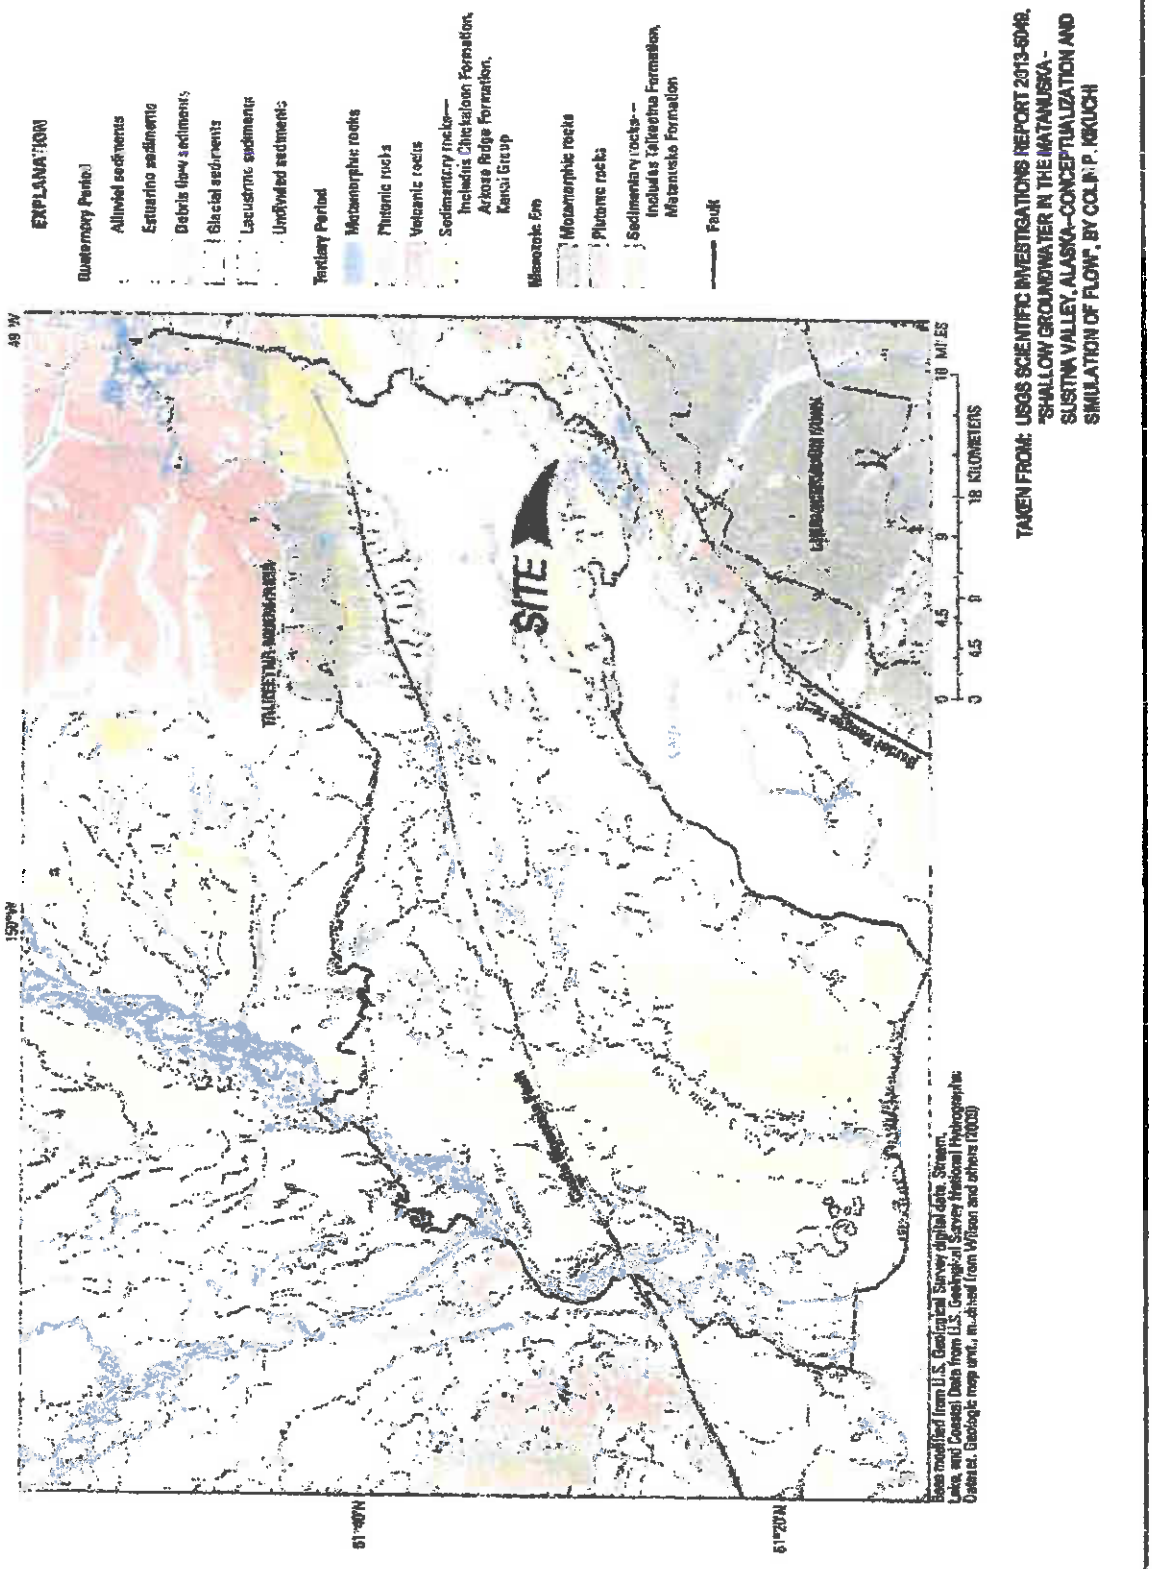
outflow from glaciers located to the northeast of the Talkeetna Mountains (also shown on Figure 4). Reference to Figure 5 will indicate that this area of recharge for the Matanuska-Susitna Valley is underlain by extremely permeable geologic materials (glacial sediments and alluvial sediments). Water flowing from the Talkeetna Mountains and into the Little Susitna River, including the water in the river, easily percolates down into these very permeable sediments, resulting in a regional flow of groundwater directly to the area near the mouth of the Matanuska River and the easterly end of the Knik Arm--this is graphically illustrated on Figure 4.

As discussed, the area in which the bulk of the groundwater recharge occurs to the glacial outwash sands and gravels that comprise the aquifer in the area of the proposed monofill lies approximately 20-miles to the north, along the Little Susitna River, at the base of the Talkeetna Mountains. This fact, along with the fact that precipitation and evaporation amounts are essentially equal in the monofill area, is in direct contradiction to JAM's statements that as many as 1-5 inches of groundwater recharge will occur at the location of the proposed monofill. He states that, for the 30+ acre surface area at the top of the fill structure, this translates to 800,000 to 4 million gallons per year of infiltration and thus, the same volume of leachate. If that were to be true, then the water balance (precipitation v/s evaporation) that indicates very little or no infiltration into the monofill indicated by the 88 years (1917-2005) of meteorological data collected by the Matanuska AES (Appendix B) is incorrect. This is unlikely. JAM implies that that local precipitation provides significant recharge to the local aquifer, and that is incorrect.

EXAMPLE OF IMPACT ON GROUNDWATER BY LEACHATE PRODUCED AT AN ALASKA MONOFILL LOCATED IN AN AREA OF HIGH PRECIPITATION AND LOW EVAPORATION

M&A reviewed the leachate-production potential for an existing monofill presently in operation at Seward, Alaska, on the Kenai Peninsula, and it's impact on the underlying aquifer. The Seward Monofill/Landfill (SMF) is owned by the Kenai Peninsula Borough Solid Waste Department. It is located at 3200 Diamond Boulevard, three miles north of downtown Seward, in the NE 1/4 of Section 28, T1N, R1E, S.M. AK. The current ADEC Permit, SWZA031-17, expires in April 2017. M&A contacted the Environmental Coordinator for the monofill, Lainie Hughes, on both March 7, 2014 and March 21, 2014 for pertinent data pertaining to the monofill-Ms. Hughes' telephone number is 907-262-9667. Ms. Hughes summarized the monofill and surrounding area as follows:

- The SMF is located immediately adjacent to, and downgradient of, a closed (1993) municipal solid waste (MSW) landfill;
- Both the SMF and the MSW landfills are unlined;
- Sampled groundwater monitoring wells are located upgradient (1 well: MW-4) and downgradient (1 well: MW-6). An additional well (MW-1), also located downgradient, is used only for water depth measurements.



MADDOX & ASSOCIATES, INC. 39371 SAN THOMAS CT. MURRIETA, CA 92562 (951) 805-1100	MATANUSKA - SUSITNA VALLEY ALASKA	FIGURE 5 HYDROGEOLOGIC FRAMEWORK OF THE MATNUSKA - SUSITNA VALLEY, ALASKA	DATE: 04/09/14 SCALE: AS SHOWN REVISED:

- No contaminants of concern have historically been detected in the wells above EPA Water Quality Standards, since monitoring began in 1989;
- Neither the closed MSW landfill nor the SMF are lined;
- Ms. Hughes stated that they do not have a groundwater contamination problem at the SMF site.

The Kenai Peninsula Borough Solid Waste Department web site contains a description of the SMF (Appendix G). The SMF is located along the edge of the Resurrection River in an area of high water table and highly permeable soils. The site was originally established by the City of Seward and operated as an open landfill for many years. The Borough assumed site operations in 1974 and operated it as the Seward Landfill. In 1919, due to initial space limitations, it was turned into a transfer facility (STF) with wastes hauled to the Central Peninsula Landfill (CPL). This proved too costly, so the original inert landfill site was enlarged in area and, in 1997 the SNF began operation.

The monofill accepts inert waste such as appliances, scrap metal, junk vehicles, construction demolition (C/D), and some landscaping and wood (L/W). Wood wastes received at the site are burned several times a year.

The groundwater monitoring wells are sampled once annually, and sampling is contracted-out to Shannon & Wilson, Anchorage, Alaska. Ms. Hughes supplied M&A with a copy of the most recent round of monitoring, conducted on October 29, 2013 (Appendix H). The October 29, 2013 monitoring round consisted of water level measurements from the three wells (MW-1, MW-4, and MW-6), and analytical sample collection from two wells (MW-4 and MW-6). The depth to water is approximately 9-feet below the ground surface in the immediate area of the SMF, with a southeasterly groundwater flow direction; the SMF is immediately downgradient from the closed MSW landfill.

Groundwater samples were collected from wells MW-4 and MW-6, and analyzed for "key indicator parameters" (essentially general minerals), 16 total metals, and 48 volatile organic compounds (VOCs). Water quality standards used to evaluate the results were:

- EPA 40 Code of Federal Regulation (CFR), Part 141 maximum contaminant levels (MCLs) (July 2009);
- ADEC 18 Alaska Administration Code (AAC) 80 drinking water MCLs (August 2012; and
- ADEC 18 AAC 80 secondary MCLs (August 2012).

Analytical Results:

Key indicator parameters were not detected in the SMF wells at concentrations greater than their respective water quality standards.

Detectable concentrations of 14 metals were reported in SMF groundwater. Iron and manganese concentrations in samples from wells MW-4 and MW-6 exceeded their

respective water quality standards, and arsenic and lead concentrations in the sample from MW-4 essentially equaled their water quality standards. Although three VOCs were detected, none of them exceeded their water quality standards.

It is of note that the two metals detected above their MCLs, Iron and Manganese, are reported by the USEPA to be present in most inert landfills. They have Secondary MCLs, and are not considered a threat to human health, public safety, or the environment. As the SMF Environmental Coordinator, Lainie Hughes, stated, there is not a groundwater contamination problem at the monofill site.

COMMENT:

Pertinent facts pertaining to the Seward Monofill (SMF):

- The Seward Monofill (SMF) is located in a Maritime climatic zone, with an average of 70.45 inches per year of precipitation (**Appendix I**), approximately five-times that of the Palmer area;
- The SMF is located immediately adjacent to, and downgradient of, a closed, unlined MSW landfill;
- The SMF is unlined;
- Groundwater occurs less than 10-feet below the base of the inert refuse;
- A considerable volume of leachate is undoubtedly produced by the SMF due to the extremely high annual precipitation rate;
- Even with the production of a considerable volume of leachate from the SMF, the aquifer, lying less than 10-feet below the base of the inert refuse, is not impacted by contamination that would present a threat to human health, public safety, or the environment.

This monofill is located approximately 120 miles to the south of the proposed monofill site. Based upon data available from the Kenai Peninsula Borough Solid Waste Department, it does not appear that there is a procedure in place nearly as comprehensive as that which will be in place at the Palmer monofill to exclude hazardous materials. Yet, with extremely high annual precipitation, no liners, and the presence of a closed MSW landfill immediately upgradient, the undoubtedly high volume of leachate produced by the SMF is not a threat to the shallow aquifer beneath the monofill. This is a very reliable example of a real-life, Alaskan monofill (containing inert refuse) that, even under extreme climatic conditions, and copious leachate production, does not contaminate the aquifer that is present at only about 9-feet below the inert refuse.

SECTION 7.3, PAGES 20-21:

We will assume JAM's estimated groundwater flow volume beneath the proposed monofill site, of 4.0 million gallons per day, to be an acceptable value. He does not appear to consider this volume of water flowing daily beneath the proposed monofill site to be a significant factor in determining the impact of any leachate possibly produced by the monofill.

The tremendous volume of water flowing beneath the monofill site each day will certainly be a significant factor when determining the effect of any leachate that may pass through the monofill and into the aquifer.

Consideration should be given to the process that occurs when any solute (leachate) is added to this aquifer. The following description is taken from Driscoll (1986). Once in the aquifer, the primary driving force for contaminant movement is created by the hydraulic gradient that produces groundwater flow. Contaminants entering the groundwater system are thus carried downgradient, forming a contaminant plume. This type of contaminant movement is called "advection". Other factors also influence the shape of the plume, including two types of "HYDRODYNAMIC DISPERSION"- mechanical mixing and molecular diffusion. These two processes cause a spreading (dispersion) of the contaminants over a much larger area than advection alone would produce and, consequently, a DILUTION of the contaminants away from the source area.

Fetter (1980) describes HYDRODYNAMIC DISPERSION as the process by which groundwater containing a solute (as is leachate) is diluted with uncontaminated groundwater as it moves through an aquifer.

On page 340, Fetter states that in a natural flow situation, there can be dispersion both longitudinally and laterally. A solute (leachate) being introduced into a groundwater flow field from a continuous point source results in a plume extending parallel to the direction of flow. The solute is less concentrated at the margins of the plume, but the concentration increases toward the source. Due to HYDRODYNAMIC DISPERSION, the plume will expand in three dimensions to fill a larger volume, but with a lower solute concentration.

The rate of advance of the contaminant front is retarded if there is a reaction between the solute and the other groundwater constituents, or if adsorption of the solute occurs. The plume of solute will then spread more slowly, and the concentration will be lower than those of an equivalent nonreactive solute.

When the tremendous flow of groundwater beneath the site is considered, and the fact that any leachate that may be produced would be of very small volume (or none), advection and hydrodynamic dispersion would dilute and reduce the concentration of any leachate that may exit the bottom of the monofill to extremely low levels--these concentrations would likely be below levels of detection.

MADDOX & ASSOCIATES CONVERSATION WITH LORI ALDRICH, OF ADEC, FEBRUARY 18, 2014

On February 18, 2014 Steve Maddox called Lori Aldrich and asked her the following question:

"Why doesn't ADEC have any problem with the construction of the proposed monofill at Palmer?"

During the conversation that followed Ms. Aldrich stated the following:

1. It meets all of the State regulations.

2. ADEC put the original CUP out for public comments and received NONE.

3. The only requirement that she insisted on was that a 10-foot separation be maintained at all times between the refuse and the underlying groundwater. She wants to see a final demonstration of this separation.

4. Only inert refuse will be placed in the monofill.

5. She visited the Birchwood site (the material to be deposited at the Palmer monofill site), near Chugiak, and examined the residual waste at that location--she says that it will make excellent cover material for the following reasons:

   a. It will compact well.

   b. It will efficiently retard the infiltration of precipitation.

6. Due to the "sub-desert" climate, with little annual precipitation, she believes that VERY LITTLE leachate will be produced by the monofill.

7. ADEC does not require groundwater monitoring for inert landfills in areas where precipitation is less than 25-inches annually--the Palmer area has approximately 15-inches annually. THEY DO NOT EXPECT THE PRODUCTION OF MUCH LEACHATE AT THE PALMER MONOFILL SITE.

8. If ADEC felt that the Palmer monofill would present a threat to groundwater, they would require groundwater monitoring--they do not require monitoring at this proposed site.

9. The gleaning of deleterious/hazardous materials from the refuse by CRS prior to landfilling at the Palmer site will prevent the introduction of hazardous compounds into the underlying aquifer, if conducted per their Operations Plan.

Additionally, I asked her if she thought that significant recharge to the aquifer presently occurs at the site of the proposed monofill (as implied by James Munter), or if the very significant volume of groundwater (>6,000,000 gallons per day) that passes under the monofill site results from recharge at a significant distance from the site. She agreed with me that only a small amount of recharge is due to on-site precipitation, and that most of the recharge occurs in the surrounding mountains (the Talkeetna Mountains). She agreed that even under current conditions, without the presence of the proposed monofill

structure, the local recharge volume to the aquifer (through the on-site sands and gravels) is minimal and insignificant. She further agreed that if the very small volume of leachate that may pass into the aquifer from the monofill were added to the tremendous volume of groundwater passing beneath the site daily, it would essentially amount to a "spit-in-the-ocean"--this was my phrasing, but Ms. Aldrich agreed with it.

Ms. Aldrich stated that her comments could be discussed with others, as she was a public employee.

SECTION 8.0 GROUNDWATER MODELING PAGES 21-25

Mr. Dan Young, of Terrasat Environmental has conducted additional contaminant transport modeling. It will be submitted separately.

GUARD WELLS PAGE 26

The subject of guard wells has been previously addressed in this document.

SECTION 9 CONCLUSIONS

To address JAM's response to M&A's Conclusions Section would be repetitious, so we will not do so.

CONCLUDING PARAGRAPH

JAM stated that M&A's concluding paragraph in the December 13, 2013 report stating that the proposed facility "will not pose a threat to the underlying aquifer" is not sufficiently supported by data or analysis and should not be relied upon.

In actuality, the majority of JAM's critique of the December 13, 2013 is not supported by fact. The responses provided in the present document support the conclusion that the proposed monofill will not pose a threat to the underlying aquifer.

APPENDIX C:

MATANUSKA AES AVERAGE EVAPORTION 1917--2005

Evaporation Stations

Standard daily pan evaporation is measured using the four-foot diameter Class A evaporation pan. The pan water level reading is adjusted when precipitation is measured to obtain the actual evaporation. Most Class A pans are installed above ground, allowing effects such as radiation on the side walls and heat exchanges with the pan material. These effects tend to increase the evaporation totals. The amounts can then be adjusted by multiplying the totals by 0.7 or 0.80 to more closely estimate the evaporation from naturally existing surfaces such as a shallow lake, wet soil or other moist natural surfaces.

Many stations do not measure pan evaporation during winter months. A "0.00" total indicates no measurement is taken.

Stations marked with an asterisk (*) have estimated totals computed from meteorological measurements using a form of the Penman equation.

Evaporation Stations

Standard daily pan evaporation is measured using the four-foot diameter Class A evaporation pan. The pan water level reading is adjusted when precipitation is measured to obtain the actual evaporation. Most Class A pans are installed above ground, allowing effects such as radiation on the side walls and heat exchanges with the pan material. These effects tend to increase the evaporation totals. The amounts can then be adjusted by multiplying the totals by 0.7 or 0.8 to more closely estimate the evaporation from naturally existing surfaces such as a shallow lake, wet soil or other moist natural surfaces.

Many stations do not measure pan evaporation during winter months. A "0.00" total indicates no measurement is taken.

Stations marked with an asterisk (*) have estimated totals computed from meteorological measurements using a form of the Penman equation.

Click on a State:

17.46 in x 0.8 = 13.968 = 14.0

APPENDIX D:

MATANUSKA AES FREEZE/FROST OCCURRENCE DATA

Freeze / Frost Occurrence Data

All probabilities in whole percent. See notes for probability level description.

- Indicates the probability of occurrence of threshold temperature is less than indicated probability.

Notes:

(1) Probability of later date in spring (thru Jul 31) than indicated.

(2) Probability of earlier date in fall (beginning Aug 1) than indicated.

(3) Probability of longer than indicated freeze free period.

(4) Probability of Freeze/Frost in the yearly period (percent of days with temperatures at or below the threshold temperature).

The sunrise/set charts don't say anything about sunniness or cloudiness, just when the sun up or down.

Frost Dates

A majority of USA stations have freeze/frost data. The percentages indicate how likely it is that a frost will occur.

For **autumn** the percentages show the likelihood of the first frost before the the given date. For example, a 10% value for September 30th means that there is a 10% chance that there will be a frost before that date. This is the same as saying there is a 90% chance that the first frost of the year will occur on or after that date.

For spring the percentages show the likelihood of that the last frost before the given date. For example, a 90% value for March 1 means that there is a 90% chance that there will be no more frost after this. In other words there is only a 10% chance that another frost will occur that year.

For some warm locations, the before and after dates are close together and may occur in the same season, usually winter.

Rankings & Extremes

Rankings are based on annual averages. Not every station reports every statistic, so the rankings are based only on those that do report. For example, if a station doesn't report high temperature, it is not ranked for that.

We'll add some ranking lists to these pages in the near future.

Heating and Cooling Degree Days

These are derived from the temperature data. Simply put, they show how hard your furnace or air conditioner has to work to maintain a comfortable interior temperature. See the Wikipedia entry for more detail.

APPENDIX E:

PERCOLATION TEST DATA FOR PROPOSED PALMER MONOFILL SITE

ENVIRONMENTAL MANAGEMENT INCORPORATED

July 10, 2013

Central Monofill Services
311 N. Sitka Street
Anchorage, AK 99501
Attn: Shane Durand

RE: **CMS Proposed Monofill Site, Palmer Alaska**

Subj: **Insitu Soil Percolation Tests**

This letter describes the results of the preliminary percolation tests performed on July 1, 2013, at the proposed Palmer Monofill site. Aaron Acena of Environmental Management, Inc. (EMI) conducted the tests under the oversight of Larry Helgeson. The standard 6-inch falling head pressure test that is recommended by ADEC was used to complete the tests. Boreholes were dug to a depth of approximately 2' in 3 areas on the property which appeared to represent "native" soil conditions on site that would be found under the monofill. Holes 1 and 2 were located within 50 ft. of each other on the south end of the property and a 3rd hole was dug closer to the west/central area of the property in a flattened zone. Holes were prepped with 2 inches of gravel at the base and allowed to soak for 1-2 hours before the test. Hole 3 exhibited water movement that qualified as ready to test "as is" without soaking. Holes 1 and 2 indicated additional soaking would be required before a percolation test could be finalized. The final percolation rate will likely be slower than the preliminary tests indicate. Preliminary percolation rates were taken from an average of the last three readings taken from each hole and are listed in Table 1.

Table 1

Location ID	Percolation Rate (min/in)
Hole 1	41
Hole 2	81
Hole 3	7

Sincerely,
Environmental Management, Inc.

SEWARD MONOFILL/LANDFILL (SMF)

(907) 224-5327

Open Monday thru Saturday from 8:00 AM to 5:45 PM & Sunday from Noon to 4:00 PM

Closed New Year's Day, Thanksgiving Day and Christmas Day

Location & Permits
The SMF is located at 3200 Dimond Blvd., 3 miles north of downtown Seward, in the NE ¼ of Sec. 28, T1N, R1E, S.M., AK. The current ADEC Permit, SWZA031-17, expires in April 2017.

Background
The site was originally established by the City of Seward and operated as an open landfill for many years. The Borough assumed site operations in 1974 and operated it as the Seward Landfill. Due to space limitations, in 1991 it was determined that the landfill should be relocated. Several locations were considered but all were either publicly opposed to or not suitable for landfill use. It was ultimately deemed the best course of action to close the landfill, open a Transfer Facility and haul the Municipal solid waste to the Central Peninsula Landfill. At first the majority of inert waste was hauled from Seward to the CPL but this proved too costly. The SMF began operating in 1997 as a cost effective alternative. The site sits on a 10-acre Borough owned parcel and includes the old landfill, Seward Transfer Facility (STF) and buffer property. The SMF serves about 5,000 year-round residents from Seward to Moose Pass along with numerous summer fishing businesses and cruise ships.

Construction
The SMF is located along the edge of the Resurrection River in an area of high water table and highly permeable soils. A dike was constructed along the river in 1979 and a 1,200-foot extension added in 1991 to protect the closed landfill from flooding during heavy rains.

No contracted construction was required since the areas to be utilized were already well established.

Operations
An Operator under contract to the Borough operates the site in conjunction with the STF. The Operator is responsible for supplying the equipment, manpower and supplies necessary to perform all operation and maintenance of the monofill in a safe and orderly manner. Contracted services include monitoring activities during operating hours, screening waste for hazardous waste exclusion, conducting litter cleanup, snow removal, access road maintenance and managing the monofill.

The Monofill accepts inert waste such as appliances, scrap metal, junk vehicles, Construction Demolition (C/D), and some Landscaping and Wood (L/W). Wood wastes received at the site are burned several times a year. Refrigerators and freezers are either placed in the SMF or stockpiled at the STF and shipped to recycle markets after refrigerants are removed. The removal and hauling of junk vehicles is the sole responsibility of the Operator.

Operational hours are Monday through Saturday from 8:00 AM to 5:45 PM and Sunday from Noon to 4:00 PM. An estimated 3,100 cubic yards is consumed annually with a projected life of 25 more years.

Monitoring
Borough staff samples three monitoring wells around the monofill perimeter annually in accordance with the ADEC permit. The Operator screens for hazardous and other types of waste for exclusion.

Fees
SMF does not have scales and charges commercial vehicles for specific waste items based on volume with a 250 cubic yard limit per job. Fees also apply to the hazardous waste management of CESQG waste. Households are not charged fees.

See "Rules" for a list of currently accepted materials and rates.

WATER MONITORING PROGRAM
2013 ANNUAL MONITORING EVENT
KENAI PENINSULA BOROUGH
SEWARD MONOFILL
SEWARD, ALASKA

1.0 INTRODUCTION

This report presents the results of our October 2013 groundwater monitoring at the Kenai Peninsula Borough's (KPB) Seward Monofill (SMF) in Seward, Alaska. Monitoring activities were conducted in accordance with our March 2008 Quality Assurance Project Plan (QAPjP). This is the 2013 annual round of monitoring, and was conducted by Shannon & Wilson on October 29, 2013.

This report summarizes the results of our field work, laboratory analysis, and data interpretation. Written authorization to proceed with these services, received in the form of a purchase order dated July 17, 2013, was provided by KPB Solid Waste Department.

2.0 BACKGROUND

2.1 Location

The SMF is an active inert waste landfill located in Seward, Alaska. The facility is located approximately 3 miles north of Seward, within the northeast 1/4 of Section 28, Township 1 North, Range 1 West, Seward Meridian, Alaska. The Resurrection River borders the site to the northeast. A vicinity map showing the project location is included as Figure 1.

2.2 Operational History

The SMF is adjacent to the Seward Landfill (SwdLF), which was established by the City of Seward in the late 1950's and operated as an open dump for numerous years. Operation of the landfill was assumed by the KPB in 1974, and it was closed in 1993. The SMF was opened in 1997 to accept inert waste including wood, land clearing debris, large scrap metal, vehicles, and construction and demolition debris. The site is a 5-acre portion of a larger Borough parcel, operated in conjunction with the Seward Transfer Facility. The remaining portion of the Borough parcel consists of the closed SwdLF, a shooting range, and buffer property. The SMF operates under ADEC Solid Waste Permit SWZA031-17, expiring April 30, 2017.

2.3 Monitoring Program Overview

Annual water monitoring is presently conducted for two on-site monitoring wells. The monitoring consists of water depth measurements and water sample collection from Monitoring Wells MW-4 and MW-6. Water depth measurements are also collected from

Monitoring Well MW-1. Monitoring Wells MW-1 and MW-4 were installed in 1989; and Monitoring Well MW-6 was installed in 1997. Baseline data for this report consist of historical sample results dating back to July 1993 for Well MW-4 and November 1997 for Well MW-6.

Well MW-4 serves as a background well and is located northwest of the monofill boundary. Well MW-6 serves as the compliance well and is located southeast of the monofill boundary.

The Alaska Department of Environmental Conservation (ADEC) requested in a January 9, 2007 letter that future SMF monitoring reports include statistical analysis. Results of the statistical analyses are included in Appendix E.

3.0 OCTOBER 2013 WATER MONITORING

The SMF monitoring event was conducted on October 29, 2013 and consisted of water level measurements from three wells (MW-1, MW-4, and MW-6) and analytical sample collection from two wells (MW-4 and MW-6).

3.1 Groundwater Flow Data

Groundwater elevations were measured in the monitoring wells at the site on October 29, 2013. The depth to water was measured by inserting an electronic water-level indicator into the monitoring well casings. The top of the well casings serve as the reference points for depth to water measurements, which were recorded to the nearest 0.01 foot. The water-level indicator was decontaminated prior to insertion into each well. The depths to water in the monitoring wells are listed in Table 1.

The groundwater flow direction, determined using water depth and survey data from the SMF wells, is to the southeast at a gradient of approximately 0.2 percent which is consistent with historical results. The approximate groundwater flow direction is shown in Figure 2. Hydrographs depicting historical water level trends for Monitoring Wells MW-1, MW-4, and MW-6 are included in Figure 3.

3.2 Groundwater Sampling

Prior to sample collection, the wells were purged of at least three well volumes with disposable bailers. Purgewater was discharged directly to the ground surface. Water quality parameters, including temperature, pH, and specific conductance, were measured after removal of each well volume using a portable Hanna field instrument. As a quality control measure, one duplicate groundwater sample, designated Sample MW-7, was collected from compliance Well MW-6. The purging and sampling details and final water quality readings are listed in Table 1, and field water sampling logs are included in Appendix A.

Analytical groundwater samples were placed in laboratory-supplied containers with the appropriate preservatives. The volatile sample vials were filled first with zero headspace to minimize the loss of volatile compounds. The turbidity samples were delivered to SGS North America Inc. (SGS) of Anchorage, Alaska using chain-of-custody procedures. The remaining

analytical samples were placed in a chilled cooler and delivered by overnight courier to Energy Laboratories, Inc. (Energy) of Billings, Montana using chain-of-custody procedures.

4.0 LABORATORY ANALYSES

The laboratory results are summarized in Table 2, with laboratory data reports included in Appendix B. Historical analytical results are included in Appendix C, and graphs of historical and current analytical results are included in Appendix D.

4.1 Analytical Testing Parameters

The groundwater samples collected from Monitoring Wells MW-4 and MW-6 were analyzed for key indicator parameters, 16 total metals, and 48 volatile organic compounds (VOCs). The key indicator parameter list for this site consists of alkalinity, chemical oxygen demand (COD), chloride, conductivity, cyanide, nitrate as nitrogen, pH, sulfate, total dissolved solids (TDS), total organic carbon (TOC), total suspended solids (TSS), and turbidity. The total metals list for this site consists of arsenic, barium, cadmium, calcium, chromium, copper, iron, lead, manganese, mercury, nickel, potassium, selenium, silver, sodium, and zinc.

4.2 Discussion of Analytical Results

Although not required for detection monitoring, SMF groundwater results are compared water quality standards as a means of providing additional information regarding SMF groundwater quality. The analytical results are compared to the following federal and state groundwater quality standards:

- Environmental Protection Agency (EPA) 40 Code of Federal Regulation (CFR) Part 141 maximum contaminant levels (MCLs) (July 2009);
- ADEC 18 Alaska Administration Code (AAC) 80 drinking water MCLs (August 2012); and
- ADEC 18 AAC 80 secondary MCLs (SMCLs) (August 2012).

The following sections summarize the current analytical sampling results, with an emphasis on detected concentrations that exceed water quality standards.

4.2.1 Key Indicator Parameters

Key indicator parameters were not detected in the SMF wells at concentrations greater than their respective water quality standards. The laboratory, however, reported the highest values to date for alkalinity in Well MW-6. Conversely, TSS and turbidity concentrations in Well MW-6 remained less than historical average concentrations. Cyanide was not detected in the wells for the third consecutive sampling event. In Well MW-6, alkalinity, conductivity, and sulfate show increasing trends, while decreasing trends are observed in TDS concentrations. Other key indicator parameters are consistent with historical concentrations.

4.2.2 Total Metals

In accordance with EPA requirements, the water samples for the metals were not filtered in the field prior to analysis; therefore, metals are reported as "total" concentrations. Detectable concentrations of 14 metals were reported in SMF groundwater.

Iron and manganese concentrations in samples from Wells MW-4 and MW-6 exceed their respective water quality standards, and arsenic and lead concentrations in the sample from background Well MW-4 equal or exceed the water quality standards. Calcium and sodium concentrations in Well MW-6 show increasing trends, whereas concentrations of chromium and nickel in background Well MW-4 show decreasing trends. The remaining metal concentrations reported for the wells are within historical range.

4.2.3 Volatile Organic Compounds

Three VOCs were detected in the October 2013 samples from SMF. Estimated (J-flagged) concentrations of dichlorodifluoromethane and 1,1,1-trichloroethane were measured in the primary and duplicate samples from Well MW-6. This is the first event where concentrations of dichlorodifluoromethane and 1,1,1-trichloroethane were detected at the site. Trichlorofluoromethane was measured in the primary and duplicate samples from Well MW-6 and Well MW-4. However, the reported concentrations are within historical range and generally the same order of magnitude as values reported in prior sampling events. No other VOCs were detected in background Well MW-4 or compliance Well MW-6.

5.0 STATISTICAL ANALYSIS

The regulations require statistical analyses of laboratory data. Both historical and current water quality data were used for the statistical evaluation. The objectives of the statistical analyses of the SMF groundwater data are to evaluate concentration trends in the site's wells, statistically quantify groundwater characteristics upgradient and downgradient of the monofill, and select appropriate statistical procedures for future analyses. In the context of the detection monitoring program, the statistical analyses are used to determine if target analyte concentrations downgradient of the landfill statistically exceed those measured in designated background well.

5.1 Background and Compliance Wells

The statistical analysis dictates that individual monitoring wells are designated as compliance wells or background wells. Based on groundwater flow data, Well MW-4 is upgradient of the monofill mass and is representative of background conditions. As shown on Figure 2, Well MW-6 is downgradient of the monofill mass and is designated as the compliance well.

5.2 Statistical Methodologies

Statistical methodologies used to analyze the groundwater data from SMF are in accordance with 18 AAC 60.830 and are based on guidance documents issued by the EPA (EPA 2009). The

prediction limit method is used to statistically evaluate constituents in the background and compliance monitoring wells at SMF. A summary of well statistics is included as Appendix E.

The first step of the statistical evaluation was to summarize the sample size and percentage of non-detectable results for each constituent from the eight wells, to identify statistical procedures. Descriptive statistics including maximum value, minimum value, mean, standard deviation, skewness, and probability correlation. Because the project data are likely to be log-normal, the descriptive statistics listed in the summary of well statistics in Appendix E were also calculated after transforming the data to the natural logs of the concentrations.

The groundwater detection monitoring procedure adopted for the KPB database consists of calculating an upper prediction limit at the 5 percent significance level (α) from background well data for each parameter. If the background well data are approximately normally or log-normally distributed, a parametric upper prediction limit is calculated; otherwise, a non-parametric upper prediction limit is calculated. The non-parametric upper prediction limit defaults to using the maximum background level as the prediction limit. If the percentage of non-detects in the background well data are between 15 and 50 percent and the data are approximately normally or log-normally distributed, the Kaplan-Meier adjustment for non-detects is used to calculate the mean and standard deviation of the data. If the percentage of non-detects exceeds 50 percent, non-parametric prediction limit methods are used. The prediction limits value represent the anticipated ("predicted") range of future measurements within the specified confidence level.

The current sampling round values from the compliance wells are compared to the upper prediction limit (1-of-1 test in the *Unified Guidance* terminology). If the current analyte concentration for a given compliance well exceeds the upper prediction limit, we conclude that there is statistical evidence of an increase over background levels at that well.

5.3 Statistical Analyses Summary

Table 4 lists those parameters and compliance wells that statistically exceed background concentrations, using Monitoring Well MW-4 as the background well. It is noted that a parameter for a given compliance well will not be considered to statistically exceed background concentrations unless that parameter is detected in the current sample from that well.

Based on our analyses, four parameters statistically exceed background concentrations. The individual parameters are the KIPs alkalinity, calcium, conductivity, and sulfate, all of which appear to be showing increasing trends in the compliance well.

The trichlorofluoromethane and chloride concentrations are qualitatively greater than background concentrations but do not exhibit a statistical variance due to elevated background hits for each of the parameters in the background well. However, these compounds may be considered to exceed background levels using the double quantification rule (See Section 6.2.2 of the *Unified Guidance*):

6.0 QUALITY CONTROL

Quality control (QC) measures are conducted in general accordance with the 2013 SMF QAPjP, and the data quality objectives (DQO) are outlined in the SMF and project laboratory's QAPjP.

6.1 Quality Control Samples

Data quality for this project was assessed using field QC samples and internal laboratory procedures. The field and laboratory data collected during the current monitoring period were checked for accuracy and precision. Field QC included one duplicate analytical sample and one trip blank. Internal procedures employed by the laboratory included method blanks, laboratory control samples (LCS), matrix spikes/matrix spike duplicates (MS/MSD), and surrogates. LCS, MS/MSD, and surrogate quality assurance data and qualifiers not meeting laboratory's DQO are noted in the laboratory reports included in Appendix B.

The project laboratory prepared a trip blank sample that accompanied the sample containers during transport. No VOCs were detected in the trip blank, suggesting that the samples were not cross-contaminated during storage or transport.

Method blanks were prepared and analyzed by the project laboratory. Iron, lead, zinc, turbidity, and TSS were reported in the method blank. None of the project sample concentrations for these analytes was within five times the concentration reported in the method blank; therefore the data are considered usable.

6.2 Data Quality Objectives

Analytical data are checked for accuracy, precision, and completeness to assess compliance with numerical DQO specified in the QAPjP. The review includes field duplicate samples, LCS, MS/MSDs, and surrogate spikes, as applicable.

6.2.1 Precision

Precision is evaluated by the relative percent difference (RPD) values for the duplicate analytical samples and MS/MSD samples. The numerical DQO for precision is 30 percent RPD.

The precision results for the primary and duplicate analytical samples, Samples MW-6 and MW-7, respectively, are shown in Table 3. The RPDs for turbidity, arsenic, barium, chromium, iron, manganese, mercury, and zinc are greater than 30 percent. The metals results are within the range of historical results, and concentrations for the duplicate sample are within two times the concentrations reported for the primary sample. Therefore, the data are considered useable for the intended purpose.

The RPD values for the MS/MSD samples were reviewed. The RPDs for the MS/MSD samples are less than 30 percent.

6.2.2 Accuracy

Accuracy was evaluated using the percent recoveries reported by the laboratories for surrogate spikes, matrix spikes, and laboratory control spike samples. The DQO is +/-30 percent (70 to 130 percent recovery) for metals, and are analyte-specific for VOCs and other analytes.

The laboratory data reports indicate that the LCS and/or LCSD recoveries are within the project DQOs. The MS and/or MSD recoveries for calcium, iron, and cyanide are outside their respective DQOs. The calcium and iron concentrations reported in the project samples are within historical range, and cyanide was not detected in the project samples. The other reported MS/MSD recoveries are within the project DQOs. Therefore, the project results are considered useable.

6.2.3 Completeness

The completeness DQO is 95 percent. Based on the precision and accuracy reported for the project data, the October 2013 data satisfy the completeness DQO.

7.0 SUMMARY AND CONCLUSIONS

Groundwater elevations, water quality measurements, and analytical samples were collected from Monitoring Wells MW-4 and MW-6 during the 2013 annual monitoring event. A water level measurement was also collected from Monitoring Well MW-1. The data indicate that the groundwater flow direction at the site is generally to the southeast.

Iron and manganese concentrations in samples from the background and compliance wells exceed applicable water quality standards, and arsenic and lead concentrations equal or exceed applicable water quality standards in the sample from the background well. Key indicator parameters were not detected at concentrations greater than the applicable water quality standards. The samples contained a total of three VOCs. This is the first SMF sampling event in which dichlorodifluoromethane and 1,1,1-trichloroethane have been detected. Trichlorofluoromethane was detected in both background and compliance wells at concentrations within historical range. No VOCs exceed the water quality standards.

In accordance with requirements for the site's detection monitoring program, statistical analysis was conducted to evaluate potential differences between parameter concentrations in designated compliance and background wells. Statistical analyses conducted using the historical monitoring well data indicated that five parameters statistically exceed background concentrations. None of the reported concentrations of these parameters exceeds water quality standards.

The next monitoring event is scheduled for October 2014. In accordance with the ADEC's October 7, 2013 letter, analytical samples will be collected from Wells MW-1, MW-4, and MW-6.

8.0 CLOSURE/LIMITATIONS

This report was prepared for the exclusive use of our client and their representatives. The findings we have presented within this report are based on limited research, sampling, and analyses. As a result, the analyses and sampling performed can only provide you with our professional judgment as to the environmental characteristics of this site, and in no way guarantee that an agency or its staff will reach the same conclusions as Shannon & Wilson, Inc. In addition, the tests were intended to detect the absence or presence of only those parameters for which analyses were performed. No conclusions are inferred as to the presence or absence of compounds other than those for which tests were performed. The data presented in this report should be considered representative of the time of our site assessment. Changes due to natural forces or human activity can occur on the site. In addition, changes in government codes, regulations, or laws may occur. Because of such changes beyond our control, our observations and interpretations may need to be revised.

Copies of documents that may be relied upon by our client are limited to the printed copies (also known as hard copies) that are signed or sealed by Shannon & Wilson with a wet, blue ink signature. Files provided in electronic media format are furnished solely for the convenience of the client. Any conclusion or information obtained or derived from such electronic files shall be at the user's sole risk. If there is a discrepancy between the electronic files and the hard copies, or you question the authenticity of the report please contact the undersigned.

Shannon & Wilson has prepared the attachment in Appendix F, "Important Information About Your Geotechnical/Environmental Report," to assist you and others in understanding the use and limitations of our reports.

You are advised that various state and federal agencies (ADEC, EPA, etc.) may require the reporting of this information. Shannon & Wilson does not assume the responsibility for reporting these findings and therefore has not, and will not, disclose the results of this study except upon your authorization or as required by law.

We appreciate this opportunity to be of service. Please contact Shayla Marshall or the undersigned at (907) 561-2120 with questions or comments concerning the contents of this report.

REPORT SUBMITTAL

All work performed during the planning of this project, the interpretation of data collected, and the preparation of this report was done according to the accepted standards of the profession. Tot the best of my knowledge, all of the data presented in this report are accurate. The stated conclusions are based upon a finite amount of data available– additional data, if available, may result in modification of some of the conclusions presented herein.

Respectfully submitted,

Steve Maddox

RE: CMS Conditional Use Permit Response to J.A. Munter Consulting, Inc. Application Review of February 7, 2014

At your request, TERRASAT reviewed comments from the Borough's consultant. The following is a summary and response of Mr. Munter's comments.

On page 1, Mr. Munter states "there is no specific mention of having worked in Alaska", referring to Mr. Maddox. Mr. Maddox is evaluating the hydrogeology of Palmer's pro-glacial outwash, which behaves like braided river deposits. Similar deposits occur around the world and are very common in California, where Mr. Maddox lives.

Mr. Munter (pg. 1) states, "The site conceptual model in this report does not comply with Alaska guidance...". The ADEC guidance for conceptual models was never intended to be used for groundwater modeling. The ADEC conceptual site model guidance is designed to help ADEC staff in Contaminated Sites determine how to close a contaminated site. Mr. Maddox's report generally follows the American Society of Testing Materials guidance (D5447-04), Application of a Groundwater Flow Model to a Site-Specific Problem. The Maddox and Associates report clearly states their assumptions and provides the conceptual data required to verify their calculations.

On page 2, Mr. Munter confuses the issue about the definition of inert. ADEC, in their solid waste regulations 18AAC60, defines inert waste (pg. 109) to mean "solid waste that has a low potential to pollute air or water, and that does not normally attract wildlife". Their definition goes on to include construction and demolition waste. This is the correct, regulatory definition to use when regulating the proposed monofill.

Mr. Munter states, "Other materials disposed of at inert monofills will eventually rot, decay and leach constituents into groundwater". Mr. Munter fails to provide facts to support his claim.

1. He provides no scientific basis to support his statement.

2. Decision makers deserve facts and a technical basis to understand processes.
3. Agricultural Experimental Station weather station data show evaporation is greater than precipitation in the Palmer area.

Mr. Munter's statement is inconsistent with these facts.

Mr. Munter (pg. 2) summarizes a 1995 study conducted for the EPA. The report states:

> "Most of this information was compiled from the literature by the National Association of Demolition Contractors (NADC); a small number of other readily available sources were used as well. These source documents provide only snapshots of the C&D waste stream in specific locations and at specific points"

The processes at the studied sites are different from the proposed conditional use permit in Palmer. The studied sites did not show that hazardous materials were removed from the construction and demolition waste. One of the sites was in Florida, which has a subtropical climate. Another site was in Vermont with a maritime climate. The comparison of different waste deposited in different climates with different geology is inappropriate to understand the physical process that will occur in Palmer.

Mr. Munter goes on to discuss an Ohio study. Ohio has a much different climate than Palmer. More importantly, the geology is much different in Ohio, where continental glaciation dominated. In Palmer, alpine-type glaciers dominated, leaving massive sand and gravel deposits to form aquifers. These massive sand and gravel aquifers have a high capacity flow, creating significant dilution of potential leachate. In Ohio, leachate would be expected to develop, because of the higher precipitation rates and longer season of thawed ground. Ohio leachate would also be expected to have higher concentrations because the massive sand and gravel aquifers are not present.

TERRASAT investigated the uncontrolled Poppy Lane landfill near Kenai, Alaska in 1986. This landfill is in outwash sand and gravel deposit, like the Palmer site. The climate in Kenai is similar to Palmer. TERRASAT located buried drums and directed excavations to exhume and examine the drums. We found little evidence of leachate formation in the landfill. We found cardboard milk cartons that had printing and photos as clear as cartons on grocery store shelves. The landfill was dry. The leachate we found was from decayed food, which is not part of C&D waste. These factual findings show what happens in a setting similar to Palmer.

Mr. Munter (bottom of page 2) discusses stability of wastes and entrainment of leachate if water flows through the waste. Stability is important when building on top of a landfill or emplacing a landfill next to a bluff. The Palmer monofill will be covered with topsoil and planted grass. The monofill is designed to have an 18-inch thick silt cap to prevent water from running through the waste. Mr. Munter's comments about stability are not relevant for this conditional use permit.

On the top of page 3, Mr. Munter attempts to redefine hazardous waste. Both EPA and ADEC have regulations preventing disposal of hazardous waste. By trying to redefine the meaning of hazardous, Mr. Munter is attempting to confuse decision makers rather than helping them make informed decisions.

Mr. Munter states, "Building fires are known to create compounds adverse to public health". He provides no information to support his opinion. He also fails to provide a significant nexus that this type of material will be included in the monofill. More importantly, Mr. Munter fails to discuss actual conditions that are likely to occur within a monofill with an 18-inch silt cap in a semi-arid climate with more evaporation than precipitation.

Mr. Munter offers an opinion that leachate will result in measurable quantities of contamination. No facts are offered to support this statement. Since Mr. Munter failed to provide a technical basis for his opinions, TERRASAT used Mr. Munter's estimates of groundwater conditions to test his opinion and provides an evaluation of his assumptions (refer to the appendix). We found that Mr. Munter's assumptions are without merit. Our conclusions are included in the appendix, along with calculations that support our conclusions.

Mr. Munter states the seasonal high groundwater level has not been determined at the site. To his credit, he most likely has not seen the data. Water level measurements for the last 12 months show that the seasonal variations are in the one-foot range. The monofill will be at least 10 feet above the water table, eliminating saturated conditions. Capillary rise in the bottom, fine-grained sands, is less than 16 inches (Todd and Mays, 2005, pg. 48, Groundwater Hydrology, 3rd Ed.)

Mr. Munter discusses sulfate concentrations and suggests that people may get sick. We evaluated this claim with a mass balance equation using hydraulic conductivity parameters provided in Mr. Munter's review. We used his infiltration value and his aquifer thickness. These calculations show that sulfate concentrations, in his worst case, will be less than 2 mg / liter (refer to the appendix). We wonder, if Mr. Munter's figures show sulfate concentrations could increase by 2 mg / liter, why is he discussing this non-issue? Refer to the appendix for the mass balance calculations.

Mr. Munter states (pg. 3) "it would be reasonable to assume that there will be a sufficient amount of waste accumulated to generate leachate that will exceed one or more drinking water maximum contaminant levels". No evidence or facts are provided. No technical basis is provided. This is just "assumed". We tested this assumption with Mr. Munter's site parameters and found this assumption is false (refer to the mass balance calculations in the appendix).

On page 4, Mr. Munter states "is not considered reliable" referring to the following opinion of Maddox and Associates. The Maddox and Associates

statement was "it is not likely that a significant volume of liquids will pass through the monofill bottom into the water table". Weather station records show that infiltration is likely less than one inch per year. An 18-inch silt cap will provide an infiltration barrier, reducing infiltration to less than one inch per year. High evaporation rates, documented at two local weather stations, show evaporation either exceeds precipitation or is nearly the same as precipitation, shows that infiltration will be minimal, and very likely less than the range Mr. Munter provides. Using Mr. Munter's site parameters in a mass balance equation shows that Mr. Munter's statement is unreliable and wrong. We believe opinions should be supported with facts and a technical basis. Refer to the appendix for the technical evaluation of Mr. Munter's opinion.

At the bottom of page 5, Mr. Munter states "analytes do not encompass all of the water quality parameters that have been known to exceed water quality standards". He then offers total dissolved solids as an example. How is this useful to a reviewer or decision maker? This statement is like saying Mr. Munter omitted "blank", therefore all of his statements should be considered inaccurate. We evaluated each parameter Mr. Munter mentioned in his review with a mass balance equation (refer to the appendix). None of them exceeded water quality standards. Without Mr. Munter disclosing the basis for his statement, everyone should question the validity of his statement.

In a separate paper, TERRASAT evaluates the physical processes that occur in the subsurface, beginning with climate, infiltration, and leaching. Many of the potential leachates are cations or organic chemicals. These substances absorb to soil particles and carbon in the landfill. The cations form complex relations with soil particles. These processes are more abundant in organic rich soils, like a monofill with ground wood fragments. We found that if leachate were to occur in the monofill, the physical migrations would likely mitigate mobilization of contaminants before they reach ground water.

At the bottom of page 6, Mr. Munter suggests there could be parallels between monofills and septic systems. He continues to discuss separation distances. We agree. We used ADEC's mass balance model to calculate compliance with water quality standards at a separation of 50 feet from the proposed monofill. Each analyte tested showed that compliance would be achieved within 50 feet of the monofill (results are presented in a separate paper). ADEC's standard is 500 feet of separation for a landfill to a Class A water well.

Mr. Munter discusses precipitation and infiltration on page 8. He bases infiltration on the amount of precipitation. Mr. Munter is incorrect because infiltration is a function of precipitation, evaporation, evapotranspiration, vegetation inception, root uptake, soil type, vegetation type, vegetation cover or density and soil type. Infiltration is also a function of antecedent soil moisture and runoff. Ignoring these physical processes in the Palmer area and basing infiltration on one parameter is just plain wrong.

On page 7, Mr. Munter states the final cap materials for this monofill will be local sand and gravel. Engineers from EMI designed an 18-inch silt cap to cover the monofill, overlain with 6 inches of topsoil. Maddox and Associate's statement is correct and Mr. Munter's statement is factually incorrect.

The last paragraph of page 7 discusses Darcy's law and makes assumptions about saturated hydraulic conductivity and 5 inches of water passing through the monofill. Darcy's law applies to saturated flow and it is inappropriately applied here. The monofill and its cap will be in an unsaturated condition, called the vadose zone or unsaturated zone, which is above the water table. TERRASAT describes the process of infiltration in a separate paper, along with calculations using the Green-Amp equation, developed for unsaturated flow. Mr. Munter's five inches of infiltration is unrealistic to expect, based on applying an 18-inch thick silt cap for a cover and having an evaporation rate that is higher than the precipitation rate. Mr. Munter's assumptions are inconsistent with the facts and he inappropriately applies Darcy's law to describe unsaturated flow.

At the bottom of page 10, Mr. Munter states the conceptual model of Maddox and Associates does not support their conclusion. Mr. Munter provides no basis for his statement. We found the conceptual model of Maddox and Associates clear and we used their conceptual model to independently determine the validity of their modeling results. While Mr. Munter disagrees with their result, he offers no basis for his disagreement and he offers no alternate conclusion.

In summary, J.A. Munter Consulting, Inc. raises concerns that have little to no merit. We tested his assumptions and found his conclusions about water quality exceedances are invalid. For many of his opinions, he offers no facts or technical basis. We believe reviewers and decision makers require facts and a technical basis to make informed decisions. We believe Mr. Munter's review, for the most part, is wrong or misleading. His review will likely frustrate decision makers who require facts and a fair evaluation.

Sincerely,

Dan Young, President of TERRASAT Inc.

Palmer Monofill -- Monofill Infiltration Calculations Using Estimates from J.A. Munter Consulting, Inc, February 12, 2014 Letter Report

Introduction

Mr. Munter provides an opinion that leachate from the proposed monofill will be above drinking water standards for sulfate. He also opines "the usefulness of the SPLP leaching test results is limited by the unusually high Limits of Quantification reported by the lab. He claims that iron concentrations could be as high as 50 mg/l. Mr. Munter (page 6) claims that arsenic concentrations could be as high as 0.250 mg/l. On page 10, he claims benzene concentrations could be as high as 80 micrograms per liter.

This calculation sheet uses Mr. Munter's estimates of groundwater flow, infiltration, and opinions about sulfate, arsenic, iron and benzene to verify if his opinions are valid.

Assumptions

Mr. Munter appears to assume that sulfate concentrations from laboratory leaching testing will have a significant deleterious impact on down-gradient water well users. Mr. Munter's estimates are provided in the input section, along with page references and comments. He further assumes that laboratory values in a saturated container with acid added equate to leachate that would originate in an unsaturated condition without the addition of acid. We disagree.

Mr. Munter further assumes that infiltration rates will range between 1 inch per year and 5 inches per year. Both of those values are tested below with sulfate. Since the higher infiltration rate produces higher final groundwater concentrations, calculations for arsenic, iron and benzene will use the higher infiltration rate.

Mr. Munter provides a background groundwater flow rate of 4,000,000 per day (pg. 11). He does not provide the basis for this value. Mr. Munter, (pg. 9) discusses a transmissivity of 100,000 sq. ft./ day for an aquifer thickness of 200 feet, concluding this equates to a hydraulic conductivity of 500 ft per day. Using Mr. Munter's K value of 500 ft/day, a thickness of 120 feet, a cross-sectional area of 1,200 ft. and a gradient of 0.008 ft/ft, the base groundwater flow would be 4,433,543 gallons per day. This higher flow rate results in lower concentrations.

Inputs

$Q_b := 4000000 \cdot \frac{gal}{day}$

Background groundwater flow, from Munter, Feb 7, 2014, pg 9, 4th paragraph

$Q_{i\_low} := 1 \cdot \frac{in}{yr} \cdot 30 \cdot acre = 814629 \ \frac{gal}{yr}$

Low infiltration rate, through monofill, from Munter, Feb 7, 2014, pg 9, 3rd paragraph

$Q_{i\_high} := 5 \cdot \frac{in}{yr} \cdot 30 \cdot acre = 4073143 \ \frac{gal}{yr}$

High infiltration rate of 5 in/yr, through monofill, from Munter, Feb 7, 2014, pg 9, 3rd paragraph. This value is much too high according to the AES climatic station, which shows that evaporation is greater than precipitation and therefore overestimates the final concentration.

$C_{SO4} := 673 \ \frac{mg}{l}$

Highest sulfate concentration from SPLP leachate test. This value is much greater than could be expected from a monofill in a semi-arid climate and the resulting moisture in the unsaturated zone and therefore greatly over estimates the final concentration (page 3, last paragraph).

$C_{arsenic} := 0.250 \cdot \frac{mg}{l}$

Arsenic concentration suggested by Munter, Feb 7, 2014, pg 6, first paragraph.

$C_{iron} := 0.050 \cdot \frac{mg}{l}$ Iron concentration suggested by Munter, Feb 7, 2014, pg 5, last paragraph.

$C_{benzene} := 0.08 \cdot \frac{mg}{l}$ Benzene concentration suggested by Munter, Feb 7, 2014, pg 10, 3rd paragraph (80 micrograms/ liter=0.08 mg/l).

Analysis

$Sulfate_{low\_i} := \frac{Q_{i\_low} \cdot C_{SO4}}{Q_b + Q_{i\_low}}$ Final sulfate concentration with one inch of infiltration per year. This is a basic mass balance equation.

$Sulfate_{high\_i} := \frac{Q_{i\_high} \cdot C_{SO4}}{Q_b + Q_{i\_high}}$ Final sulfate concentration with five inches of infiltration per year. MCL= 250 mg/l

$Arsenic_{high\_i} := \frac{Q_{i\_high} \cdot C_{arsenic}}{Q_b + Q_{i\_high}}$ Final concentration for arsenic with 5 inches of infiltration per year. Compliance level is 0.010 mg/l.

$Iron_{high\_i} := \frac{Q_{i\_high} \cdot C_{iron}}{Q_b + Q_{i\_high}}$ Final concentration for iron with 5 inches of infiltration per year.

$Benzene_{high\_i} := \frac{Q_{i\_high} \cdot C_{benzene}}{Q_b + Q_{i\_high}}$ Final concentration for benzene with 5 inches of infiltration per year.

Results

$Sulfate_{low\_i} = 0.375 \frac{mg}{l}$ Compliance level is 250 mg/l

$Sulfate_{high\_i} = 1.871 \frac{mg}{l}$ Compliance level is 250 mg/l

$Arsenic_{high\_i} = 0.0007 \frac{mg}{l}$ Compliance level is 0.010 mg/l

$Iron_{high\_i} = 0.00014 \frac{mg}{l}$ Compliance level is 0.3 mg/l

$Benzene_{high\_i} = 0.00022 \frac{mg}{l}$ Compliance level is 0.005 mg/l

Conclusions

Mr. Munter's opinions about groundwater contamination are invalid at the proposed Palmer monofill site. Results from mass balance calculations, using Mr. Munter's aquifer properties, show that groundwater will not be significantly impacted.

Mr. Munter's opinions about inappropriate LOQ's are tested and the results show that his opinions are meaningless. As an example: If iron was present at the LOQ level, the level in the groundwater would be 1/ 2,143 of the compliance level.

Mr. Munter's opinions about sulfate leachate impacting drinking water are invalid. The highest calculated value of 1.87 mg/l should be lower because Mr. Munter underestimated groundwater flow and overestimated sulfate leaching. A more realistic sulfate concentration, using a leachate concentration of 200 mg/l and background base flow of 4,433,543 gal/day would result in a concentration of 0.1 mg/l. The deleterious effect of such a low concentration using Mr. Munter's assumptions (either 1.87 or 0.5 mg/l) is insignificant to human health or the environment. The existing background level is 47 mg/l and a compliance level of 250 mg/l.

The results of the above calculations show that the contamination issues raised by Mr. Munter are not based on fact or sound science.

RE: CMS Conditional Use Permit Vadose Zone and Groundwater Modeling Results

At your request, TERRASAT evaluated infiltration processes and potential leachate fate and transport through the proposed monofill at your Palmer property. We extended the leachate model to include groundwater migration to the property boundary, fifty feet down gradient of the proposed monofill.

Introduction

The purpose and goal of this investigation and modeling is to allow decision makers an opportunity to understand the physical processes that occur from infiltration into topsoil, silt caps, and into the proposed monofill. Three models are presented to describe the physical infiltration processes. The first model is a conceptual model that follows ASTM Standard D5447-04 (2010). The purpose of the conceptual model is to illustrate some of the physical processes that occur, as well as to show model inputs. In this case, the ASTM standard is much more appropriate for a conceptual model than using the ADEC model that is designed for closing out contaminated sites.

The second model predicts how infiltration migrates through various layers of the proposed monofill. This model supports the conceptual model and shows decision-makers where water flows and how it flows. This model is commonly used to evaluate infiltration and to determine stormwater runoff. The Green-Amp equation, developed in 1911, provides an understanding of the infiltration process.

The third model is an analytical mass balance model based on ADEC's leach field model for nitrate evaluation. This model is used to predict nitrate concentrations, in a steady-state environment, down gradient at a receptor. ADEC uses this mass balance model to permit leach fields as well as to protect down gradient drinking water users. We use this model to predict the potential

fate of contaminants that could exist within the proposed monofill. Limitations of this model are discussed elsewhere in this report in the limitations section.

Model functions

The conceptual model is used to visually explain infiltration and migration routes and processes. Model inputs are provided to understand the analytical and mass balance model.

The Green-Amp equation is used to show infiltration rates through the protective silt cap and into the first layer of the monofill. Infiltration rates vary depending on the soil properties. The upper layers of the conceptual model show the results of the Green-Amp modeling. Results of this model also explain why minimal leaching is expected from the monofill.

The mass balance model predicts long-term steady-state results at a compliance point or receptor. In this case, the compliance point or receptor is the down gradient property boundary. Analytes, or potential pollutants, were identified earlier in a SPLP laboratory leaching procedure. Two potential contaminants of concern were identified, one being sulfate and the other is manganese. Additional analytes that were below the detection limit are modeled, using an assumed concentration because no evidence exists to demonstrate that these concentrations exist. The assumed concentration is the Limit of Quantification value from the SPLP leachate testing. Results of this model, being conservative, show the maximum concentrations down gradient at the property boundary. The results predict the likelihood that analytes will comply with ADEC's drinking water standards.

General setting

The general setting for the proposed monofill is within the confines of a former gravel extraction site. The design requires a minimum of 10 feet of soil separating the monofill from the existing water table. Existing soil consists of primarily a well-drained sand. If fill is required, on-site soil material will be used such as a well-drained sand or possibly silty sand.

Seven monitoring wells were installed previously at the site. Groundwater levels were measured in July 2013 and at other times during the last 12 months. The water table generally fluctuates less than one foot. The general gradient trends south by southwest, with a gradient of 0.008 feet per feet, measured in July 2013. This groundwater gradient corresponds with the April 30, 2013 water table gradient of 0.006. The unconfined aquifer that underlies the proposed monofill consists of sand and gravel with a relatively high hydraulic conductivity. The sand and gravel deposits are the result of a previous glacier, with the site being at the terminus of a glacier. Photo interpretation shows crevasse fills from the terminus of a glacier, and evidence of massive pro-glacial runoff creating gravel fluvial deposits down gradient. Water is supplied to this aquifer primarily by infiltration from the Matanuska River.

Conceptual model

Climatic Data

The Palmer Alaska Experiment Station summarizes climatic data from 1982 through 2012. They report an average annual total precipitation of 15.94 inches and a yearly total evaporation of 18.34 inches. These measurements suggest that infiltration is -2.4 inches per year. Another way of interpreting this data is that soil infiltration does not occur.

The Palmer Job Corp has precipitation data for the periods of 1993 to 1997 and 2004 to 2012. The average precipitation for this 14-year set of data is 15.63 inches per year. This average is very close to the 15.94-inch average at the Alaska Experimental Station. The Palmer Job Corp measured evaporation rates for 1993 to 1997. The Palmer Job Corp average yearly total evaporation rate was 15.57 inches, suggesting soil infiltration could be 0.06 inches per year.

In summary, existing records suggest infiltration is minimal or non-existent. The processes of water infiltration are discussed below.

Physical soil processes

Horton and Jury, 2004, (pg. 102) describe water infiltration mass balance processes as precipitation enters topsoil. Central Monofill Services already designed a monofill cover with an 18-inch thick silt cap that is overlain with 6-inches of topsoil and planted with grass. The first process that occurs during a rainfall event is the vegetation incepts some or all of the rainfall. Rainfall in excess of inception reaches the soil and begins to infiltrate.

We assume the topsoil will be a mixture of silt, sand, organics and clay. We assume this topsoil has the texture and properties of a loam, which is a mixture of the above-mentioned materials. Sandy loam and loamy sand have a slightly lower effective porosity, so our assumption is reasonable to model infiltration into the topsoil. A loam topsoil is likely to have dual porosity. The first type of porosity is the void space between the soil particles. The second type of porosity is root cavities, insect burrows, worm burrows and other cavities left by micro-arthropods. Textbook values for total porosity of loam average 0.463. Since some of the voids are not connected, the average effective porosity is 0.434 (Todd and Mays, 2005, pg. 138). The effective porosity matches our modeling with RETC software, developed by M.Th. van Genuchten and others, 1991, for the EPA. The purpose of RETC is to simulate additional soil properties and develop a soil-water retention curve.

As water infiltrates into these voids, some of the voids fill up becoming matric water and some of the voids have trapped air and prevent infiltration into the voids. Matric water remains available for plant root uptake and later evaporation and transpiration. Water in excess of the matric water storage and inception process is taken up by plant roots, with some of the water being evaporated by

the plants (evapotranspiration) and some of the water evaporates into the air. Water in excess of these processes migrates deeper into the soil.

If infiltration rates are slower than a rainfall event, the excess rainfall begins to runoff at the surface. For a mass balance, we now describe outflow. Six-inches of soil with an effective porosity of 0.434 will require 2.6 inches of precipitation infiltration to saturate the topsoil. A statistical 10-year, 24-hour storm event is likely to produce 2.5 inches of precipitation (TR-47, 1963). Larger storms will likely have significant surface runoff, restricting infiltration. A 10-year event means ten storms of this magnitude are predicted to occur within a one-hundred-year time interval.

What happens to infiltration in excess of the above processes? The excess eventually reaches the silt horizon below the topsoil. Some of the water infiltrates into the silt layer, with the remainder running off at the topsoil-silt soil interface. The saturated hydraulic conductivity of the topsoil is higher than the silt hydraulic conductivity, thus creating a preferential pathway along the top of the silt. These processes are graphically displayed in the appendix listed as Conceptual models. Please note that Theta-S (θ_s) is the saturated porosity and Theta-R (θ_r) is the residual water content of a drained soil, calculated using RETC software.

What happens during winter and spring during breakup? Winter conditions typically bring frozen soil during October and freezing soil conditions prevail until April and even early May. Because the silt cap will have small pores or voids, soil moisture will quickly seal off the voids during winter conditions. Thus, this layer becomes impermeable for at least 6 months of the year. During breakup, the upper topsoil thaws before the deeper silt. Therefore, if infiltration from snowmelt occurs, the saturated bottom layer of the topsoil will runoff, above the frozen silt, reducing or eliminating infiltration into the frozen impermeable silt. Typically, during breakup, top soil remains frozen while snow melts and runoff occurs beneath the snow but above the topsoil.

Soil properties

The first page of the conceptual model in the appendix shows soil properties of the upper two layers, the topsoil and silt cap. Soil properties measured at Terra Firma are shown on the graphical model. The topsoil properties are computed with RETC software using dual porosity fitted to the Mualem model. Mualem's equation considers the soil as two bundles of capillary tubes connected in a series (Radcliffe and Simunek, 2010, pp. 99-100). The van Genuchten retention function is commonly coupled with the model of Mualem to calculate the unsaturated hydraulic conductivity based on the effective saturation. The results were compared to text book values for confirmation of the validity of the results. (Schwartz and Zhang, 2003, pg. 140, Radcliffe and Simunek, 2010, pg. 90, and Todd and Mays, 2005, pg. 130).

Deeper soil properties are shown on the second page of the conceptual model. Saturated hydraulic conductivities (k or K_{sat}) were measured in a permeameter at the lab of Terra Firma, in Anchorage. Silt was compacted to 80% before testing. This reasonable compaction likely represents actual site conditions. The migration path is shown on the conceptual model, if infiltration occurs. Aquifer properties are discussed in the next section.

Aquifer system

Monitoring and observation wells exist up gradient and down gradient of the proposed monofill in an unconfined aquifer. Water levels from April 30, 2013 were contoured and show a groundwater gradient of 0.006 ft. per ft. migrating south-south west. Water level data from June 2013 shows a similar trend with a gradient of 0.008 ft./ft.

Six available water well logs from the area around Canoe Lake show depths to aquifers ranging from 80 to 191 feet deep. Four of these aquifers show evidence that they are confined aquifers with static water levels at the time of drilling above the top of the aquifer. We chose to represent the aquifer thickness as 57 feet thick, based on average thickness of Brailey Hydrologic Consultants, 2011, figure 4, layer 1. Data is not available to support a thicker aquifer. A thicker aquifer would result in more dilution of the final modeling results. We assume that the lateral boundaries of the unconfined aquifer are infinite, with respect to the effects of our analytical model. While the occurrence of bedrock may create a lateral boundary, the distance is great enough to ignore for the purposes of our model.

Brailey Hydrologic Consultants, 2011, reports that an aquifer test was conducted on a pond adjacent to the Palmer pit and determined that the hydraulic conductivity of the unconfined aquifer ranges between 700 and 1,000 feet per day. TERRASAT conducted modeling in 2012 and used a hydraulic conductivity of 1,400 feet per day, calibrated to a former pond breach and the rise in Canoe Lake. J.A. Munter (2014) stated the aquifer hydraulic conductivity should be 500 feet per day but withheld a basis for this value. We believe an appropriate hydraulic conductivity is more than 1,000 feet per day but we choose to use 500 feet per day for our model to avoid arguments. A value of 1,000 feet per day, more realistic, would result in significant reduction of contaminant concentrations down gradient from the proposed monofill if leachate ever reaches the aquifer.

Infiltration Modeling

Assuming water infiltrates through the topsoil and into the 18-inch thick silt cap, what processes occur and what is the likelihood that leachate will form and migrate? Flow in the silt cap is by the process of unsaturated flow, meaning the soil voids do not fully saturate. Infiltration in the unsaturated zone is commonly modeled with the Green-Amp equation, developed in 1911 (Todd and Mays, 2005, pp. 134-139 and others).

TERRASAT used the Green-Amp equation to show infiltration rates and depth *vs.* time for the silt cap and the underlying residual C&D waste material within the proposed monofill. We found nine hours are required to migrate water through the topsoil, to reach a depth of 6 inches, during a typical Alaskan rainfall event. These results are consistent with experiments done in a local garden where a series of soil tensiometers were deployed to measure soil moisture at depths of 6 inches, 12 inches and 18 inches. Results from 10 years of monitoring revealed that vegetation inception prevented rainfall from reaching 6 inches deep after a week of rainfall in the wettest time of year.

If we ignore the topsoil, and assume precipitation reaches the silt cap instantaneously, a 24-hour storm event would infiltrate 8.8 inches into the 18-inch thick silt cap. Sixty two (62) hours are required to infiltrate through the silt cap. During the 62 hours, capillary pressures in the silt are great enough to move some of that water back up to the surface of the silt, where root uptake occurs, plus evaporation and evapotranspiration. Todd and Mays, 2005, pg. 49, state that actual capillary rise in silt ranges from 3.3 feet to 6.6 feet, much greater than the thickness of the silt cap. The results of this modeling show that very little water will infiltrate through the silt cap, in the 6 months the cap is thawed.

Combining the topsoil and silt cap, 62 + 9 = 71 hours are required to infiltrate a storm event into the residual waste. During that time, evaporation, evapotranspiration, root uptake, capillary pressure and runoff events occur, reducing the amount of water available for infiltration through the silt cap. One point worth making is that infiltration, if it occurs, is episodic, in pulses, most likely at the end of summer in the wettest time of the year. This means that flow in the unsaturated zone is transient and not steady state (continuous flow).

Since some water could infiltrate into the residual waste, we use the Green-Amp equation to describe the infiltration process within a 15-foot thick residual waste layer. Results are shown in the Appendix under the Green-Amp Modeling section. The results show that infiltration would move through 15 feet of residual waste within 4.8 hours. More importantly, this is unsaturated flow. Therefore, little time is available to leach metals or organics from the residual waste. These results explain why leachate formation is minimal to non-existent in monofills that occur in arid and semi-arid regions.

Mass Balance Model from ADEC

TERRASAT presents a third modeling evaluation of leachate moving through the monofill and down gradient to the property boundary. This model is different from the Green-Amp equation in several ways. The first difference is that the mass balance simulates leachate movement along with water flow. The second difference is the mass balance assumes saturated flow through the monofill. The mass balance also includes groundwater flow.

We made several assumptions for the mass balance model and the model itself makes assumptions. We assume, for the sake of modeling, that 2 inches of precipitation can migrate through the monofill. As discussed in the conceptual model, under the climate subheading, this value is high, resulting in higher concentrations than should be expected. The Green-Amp model shows that small amounts of water can get into the residual waste, probably much less than 2 inches.

The mass-balance model assumes saturated flow, which will not occur in a well-drained soil like residual waste in a monofill. More than 240 inches of precipitation would be required to saturate the monofill, if water could not flow out of the fill. Two hundred and 40 inches of precipitation per year is unreasonable to expect, when the annual precipitation is a mere 15 inches.

The next assumption is that the monofill occupies 35 acres and is mature. This is a worst-case scenario, where the maximum amount of fill is in the ground. We also assume that the compliance point is 50 feet down gradient from the monofill. A greater distance would provide more aquifer dilution, reducing the concentration at the compliance point. We should point out that the nearest house is more than 500 feet away, in a different aquifer, and not directly down gradient. Aquifer diffusion and dispersion processes would provide significantly more dilution 500 feet away than the results we derive.

We assume that the hydraulic conductivity of the underlying aquifer is 500 feet per day. Our opinion is that the hydraulic conductivity is greater than 1,000 feet per day, evidenced by aquifer testing and by calibrated modeling. The result of using 500 feet per day will bias the results to create a higher contaminant concentration at the ultimate receptor, the property boundary. We chose this value as a concession to avoid disputing the conductivity with J.A. Munter, who stated he thinks 500 feet per day is reasonable, even though he offered no evidence.

Aquifer thickness for our modeling is 57 feet thick. This value is the average thickness of Brailey's cross section in his model. This thickness is likely realistic, based on available data. However, some existing well logs show an aquifer that is nearly 300 feet deep. A 300-foot thick aquifer would add significant amounts of dilution. We chose to use a value that we believe is representative, even if the result is a higher contaminant concentration at the property boundary.

Mass Balance Limitations

This model assumes that leachate does not react during migration, thus over estimating concentrations at the down-gradient measuring point. The model assumes aquifer dispersion is 1.5 times the aquifer thickness. This may overestimate the results or under estimate results. Unconsolidated aquifers flow in three dimensions, longitudinal, transverse and vertical. ADEC's mass balance model accounts for the dispersion by the 1.5 times aquifer thickness.

The mass balance model assumes that the leaching and resulting plume migrate at a steady state. Climatic data and the Green-Amp model show that flow is transient, rather than steady state. With steady state, the model assumes leachate migrates continuously, resulting in higher concentrations than should be expected in this setting.

The reason we chose this model, considering its unfavorable bias to elevated results, is because this is a great screening tool. If results are elevated, more complex models can be used that consider reactions of contaminants, like biodegradation, partitioning, cation exchange, degassing and chemical reaction. The ADEC uses this model to screen for worst-case scenarios when nitrate is leached into the ground, and they ignore denitrification, degassing and bioaccumulation in their screening. Therefore, we believe this model is appropriate for a screening tool.

Contaminants of concern

Sulfate and manganese had elevated concentrations from three laboratory leachate evaluations. The laboratory procedure saturates a sample for 18 hours, adds acid to the liquid, and agitates the sample. This process is intended to create leaching in an environment that is much more aggressive than a monofill. We already demonstrated that saturation will not occur within the unsaturated zone. We also demonstrated, with the Green-Amp model, that moisture is exposed to residual waste for less than 5 hours for each cell, minimizing the potential for leachate formation.

Additional potential contaminates are evaluated with the ADEC mass balance model. These potential contaminates, shown below, are evaluated because the laboratory SPLP limits of quantification were above drinking water standards. We found no evidence to believe that these analytes had measurable concentrations, let alone that they were as high as the limits of quantification. We modeled these analytes as a screening tool, to determine if they could pose a risk to drinking water at the property boundary.

Table 1, possible contaminates of concern

Analyte	Concern
Arsenic	LOQ was 0.25 micrograms per liter
Benzene	LOQ was 0.8 mg per liter
Cadmium	LOQ was 0.1 mg per liter
Chromium	LOQ was 0.2 mg per liter
Iron	LOQ was 50 mg per liter
Pentachlorophenol	LOQ was 0.61 mg per liter
Formaldehyde	Discussed separately

Results

Mass balance screening results are shown in Appendix C, Loading from Leach Field Model. With the exception of cadmium, the above analytes, when screened

at the concentrations equaling the limits of quantification from laboratory SPLP testing, show compliance with drinking water standards at the down-gradient property boundary.

Cadmium was the exception, when modeled at the LOQ concentration. This analyte increased 0.15 micrograms per liter. While this increase is minimal, we need to consider that we are assuming that cadmium concentrations exist at the level of the LOQ. This is an assumption made for the purpose of screening or modeling. The model excludes cation fixation processes, which are very high in organic soils, like residual C&D (construction and demolition) waste with wood fragments. Cadmium is likely immobile in the monofill or at least has a very low mobility (Dragun, 1988, pg. 156 and 178).

Formaldehyde was considered for modeling until we conducted research on the fate and transport of this analyte. Neither ADEC nor the EPA has standards for formaldehyde in drinking water. According to the United States National Library of Medicine's Toxicology Data Network

> "**Formaldehyde** readily biodegrades under both aerobic and anaerobic conditions in the environment (SRC). **Formaldehyde** in aqueous effluent was degraded by activated sludge and sewage in 48-72 hr(7-11). In a die-away test using water from a stagnant lake, degradation was complete in 30 and 40 hrs under aerobic and anaerobic conditions, respectively".

If formaldehyde is present in C&D residual waste, it will be in a gaseous form. That means the total mass of formaldehyde is minimal. Without water saturation in the monofill, no significant mechanism exists to transfer the gases into the moisture that occasionally will move through the landfill. Because of the rapid degradation, if formaldehyde exists, we expect it to completely degrade before it reaches the property boundary.

Sensitivity analysis

We used reasonable parameters for our mass balance model where possible. The remaining assumptions were conservative, resulting in elevated concentrations. The results show that none of the analytes are a concern at concentrations from the LOQ of the laboratory leaching procedures. Therefore, sensitivity analyses were not conducted. If we were to conduct these sensitive analyses, values that are more liberal would be used, such as a higher hydraulic conductivity and less infiltration. The results would still show that concentrations at the property boundary would be less than our screening results.

Summary and conclusions

Three models were evaluated to explain the physical processes of water infiltration into the proposed monofill. The conceptual model shows the configuration of the monofill, the parameters that control infiltration and the infiltration pathways. We learned that existing climatic records show infiltration is unlikely to occur. If some infiltration occurs, the amount will be minor and much less than the 2 inch value we modeled. Vegetation inception prevents some rain from infiltrating the first layer of top soil.

Results from the Green-Amp model show infiltration is a slow process in both the top soil and the silt cap. Many storms without evaporation are required to infiltrate small amounts of water into the ground. Some of the infiltrated water is evaporated, some is stored as matric water for later plant use, and some comes back to the top soil by capillary pressures. For any water that migrates below the silt cap, the water will move through a residual waste cell in hours, as an unsaturated flow. This means little time is available to form leachate.

ADEC's leachate screening model shows that analytes, above detection limits from leachate studies, will be in compliance with ADEC drinking water standards. The leaching testing procedure requires water saturation, the addition of acid, and agitation to generate leachate. Those processes are absent in an unsaturated monofill.

Physical processes, such as cation fixation, sorption, and biodegradation will further reduce risks of leachate migration. In conclusion, the proposed monofill appears to be protective of groundwater sources if the monofill is constructed as modeled in the conceptual model.

Sincerely,

Dan Young

Appendix C Loading From Leachate Field Model

Arsenic Loading from Leach Field Model

Mass balance inputs for concentrations from laboratory leaching.
Calculations are based on ADEC mass balance model for septic leach fields.

$C_b := 36.1 \cdot \frac{\mu g}{l}$

Arsenic concentration in background water supply (measured from monitoring well testing)

$C_{leach} := .25 \cdot \frac{\mu g}{l}$

Hypothetically assume arsenic leaches at the LOQ Level (Level of Quantification during leachate testing). No lab data exists to validate arsenic levels would ever reach this hypothetical elevated level

$C_{infiltration} := 0 \cdot \frac{mg}{l}$

Arsenic concentration in rainfall

Leach Field design inputs

$Q_{leach} := \frac{2.0 \cdot in \cdot 35 \cdot acre}{yr} = 5204 \ \frac{gal}{day}$

Monofill effluent (2.0 in / yr infiltration) * 35 acres, total area. Two inches of infiltration is likely higher than expected (discussed in text portion of this report)

Aquifer characteristics

$k := 500 \cdot \frac{ft}{day}$

Hydraulic conductivity (based on J.A. Munter, Feb 2014, and aquifer testing by AS&G.

$b := 57 \cdot ft$

Aquifer thickness. This value is an average thickness based on modeling by Brailey Hydrologic Consultants, figure 4, layer 1, September 30, 2011. A larger thickness will create more dilution at the property boundary and lower concentrations.

$Width := \sqrt{35 \cdot acre} = 1235 \ ft$

width of existing leach field

$Area := Width \cdot b \cdot 1.5$

crossectional area of leach field * 1.5 to account for lateral dispersion and diffusion of sulfate in groundwater (following ADEC)

$Area = 105571 \ ft^2$

Cross sectional area of aquifer allowing for transverse dispersivity

$i := 0.008$

Gradient of aquifer, measured in July 2013 downgradient of ponds.

Precipitation infiltration

$i_{infiltration} := \frac{2 \cdot in}{yr} = (4.563 \cdot 10^{-4}) \ \frac{ft}{day}$

Weather records from both the Palmer Job Corps and the Alaska Extension Service show less than 1 inch of precipitation is available for infiltration. Refer to text for discussion.

$x := 50 \cdot ft$

Distance from source to receptor (property boundary)

$Area_{infiltration} := x \cdot Width$

Assumes infiltration between leach field and receptor provides infiltration to the underlying water-table aquifer

$Q_i := Area_{infiltration} \cdot i_{infiltration} = 211 \ \frac{gal}{day}$

Infiltration down gradient of monofill, between monofill and property boundary.

Results

$Q_b := k \cdot i \cdot Area = 422283 \ \frac{ft^3}{day}$

$$C_r := \frac{Q_b \cdot C_b + (Q_{leach} \cdot C_{leach}) + Q_i \cdot C_{infiltration}}{Q_b + Q_{leach} + Q_i}$$

$C_r = 36.04 \ \frac{\mu g}{l}$

Arsenic concentration at nearest receptor where $x = 50 \ ft$. The ADEC drinking water standard is 10 μg/l. Note that arsenic is already above the drinking water limit in natural concentrations and that adding more water, as infiltration, actually dilutes arsenic at the compliance point, the property boundary.

Benzene Loading from Leachfield

Mass balance inputs for concentrations from laboratory leaching. Calculations are based on ADEC mass balance model for septic leach fields.

$C_b := 0 \cdot \frac{mg}{l}$

Benzene concentration in background water suppiy (measured from monitoring well testing)

$C_{leach} := .08 \cdot \frac{mg}{l}$

Benzene Limit of Quantification for laboratory leachate proceedures. Actual on-site concentrations will be lower than this value because the soils are unsaturated and the laboratory saturated the samples for 18 hours. Benzene was not detected during all three leachate tests, so we are hypothesizing that it could be present at the lab limit of quantification only to determine what if is present.

$C_{infiltration} := 0 \cdot \frac{mg}{l}$

Benzene concentration in rainfall

Leach Field design inputs

$Q_{leach} := \frac{2 \cdot in \cdot 35 \cdot acre}{yr} = 5204 \ \frac{gal}{day}$

Monofill effluent (2in / yr infiltration) * 35 acres, total area. Two inches of infiltration is likely higher than expected (discussed in text portion of this report).

Aquifer characteristics

$k := 500 \cdot \frac{ft}{day}$

Hydraulic conductivity (based on J.A. Munter, Feb 2014 and aquifer testing by AS&G.

$b := 57 \cdot ft$

Aquifer thickness. This value is an average thickness based on modeling by Brailey Hydrologic Consultants, figure 4, layer 1, September 30, 2011. A larger thickness will create more dilution at the property boundary and lower concentrations.

$Width := \sqrt{35 \cdot acre} = 1235 \ ft$

width of existing leach field

$Area := Width \cdot b \cdot 1.5$

crossectional area of leach field * 1.5 to account for lateral dispersion and diffusion of sulfate in groundwater (following ADEC)

$Area = 105571 \ ft^2$

Cross sectional area of aquifer allowing for transverse dispersivity

$i := 0.008$

Gradient of aquifer, measured in July 2013 down gradient of the ponds

Precipitation infiltration

$i_{infiltration} := \frac{2 \cdot in}{yr} = 0 \ \frac{ft}{day}$

Weather records from both the Palmer Job Corps and the Alaska Extension Service show less than 1 inch of precipitation is available for infiltration. Refer to text for discussion

$x := 50 \cdot ft$

Distance from source to receptor (property boundary)

$Area_{infiltration} := x \cdot Width$

Assumes infiltration between leach field and receptor provides infiltration to the underlying water-table aquifer

$Q_i := Area_{infiltration} \cdot i_{infiltration} = 211 \ \frac{gal}{day}$

Infiltration down gradient of monofill, between monofill and property boundary.

Results

$Q_b := k \cdot i \cdot Area = 422283 \ \frac{ft^3}{day}$

$$C_x := \frac{Q_b \cdot C_b + (Q_{leach} \cdot C_{leach}) + Q_i \cdot C_{infiltration}}{Q_b + Q_{leach} + Q_i}$$

$C_x = 0.1 \ \frac{\mu g}{l}$

Benzene concentration at nearest receptor where $x = 50 \ ft$. The ADEC drinking water standard is 5 μg/l. The receptor is the property boundary. Partitioning processes, including adsorption and biological degredation would reduce this concentration to much less than shown.

Cadmium Loading from Leachfield

Mass balance inputs for concentrations from laboratory leaching. Calculations are based on ADEC mass balance model for septic leach fields.

$C_b := 10.9 \cdot \frac{\mu g}{l}$ Cadmium concentration in background water supply (measured from monitoring well testing)

$C_{leach} := 0.1 \cdot \frac{mg}{l}$ Hypothetically assume Cadmium leaches at the LOQ Level (Level of Quantification during leachate testing). No lab data exists to validate Cadmium levels would ever reach this hypothetical level.

$C_{infiltration} := 0 \cdot \frac{mg}{l}$ Cadmium concentration in rainfall

Leach Field design inputs

$Q_{leach} := \frac{2 \cdot in \cdot 35 \cdot acre}{yr} = 5204 \frac{gal}{day}$ Monofill effluent (2.0 in / yr infiltration) * 35 acres, total area. Two inches of infiltration is likely higher than expected (discussed in text portion of this report).

Aquifer characteristics

$k := 500 \cdot \frac{ft}{day}$ Hydraulic conductivity (based on J.A. Munter, Feb 2014, and aquifer testing by AS&G.

$b := 57 \cdot ft$ Aquifer thickness. This value is an average thickness based on modeling by Brailey Hydrologic Consultants, figure 4, layer 1, September 30, 2011. A larger thickness will create more dilution at the property boundary and lower concentrations.

$Width := \sqrt{35 \cdot acre} = 1235\ ft$ width of existing leach field

$Area := Width \cdot b \cdot 1.5$ crossectional area of leach field * 1.5 to account for lateral dispersion and diffusion of sulfate in groundwater (following ADEC)

$Area = 105571\ ft^2$ Cross sectional area of aquifer allowing for transverse dispersivity

$i := 0.008$ Gradient of aquifer, down gradient of the ponds, measured in July 2013.

Precipitation infiltration

$i_{infiltration} := \frac{2 \cdot in}{yr} = (4.563 \cdot 10^{-4}) \frac{ft}{day}$ Weather records from both the Palmer Job Corps and the Alaska Extension Service show less than 1 inch of precipitation is available for infiltration. Refer to text for discussion.

$x := 50 \cdot ft$ Distance from source to receptor (property boundary)

$Area_{infiltration} := x \cdot Width$ Assumes infiltration between leach field and receptor provides infiltration to the underlying water-table aquifer

$Q_i := Area_{infiltration} \cdot i_{infiltration} = 211 \frac{gal}{day}$ Infiltration down gradient of monofill, between monofill and property boundary

Results

$Q_h := k \cdot i \cdot Area = 422283 \frac{ft^3}{day}$

$$C_x := \frac{Q_h \cdot C_b + (Q_{leach} \cdot C_{leach}) + Q_i \cdot C_{infiltration}}{Q_h + Q_{leach} + Q_i}$$

$C_x = 11.05 \frac{\mu g}{l}$ Cadmium concentration at nearest receptor where $x = 50\ ft$. The ADEC drinking water standard is 0.005 mg/l. Note that Cadmium is already above the drinking water limit in natural concentrations. Adding a hypothetical amount of 100 micrograms per liter with inflitration increases the concentration by 0.16 micrograms per liter at the property boundary. This increase does not consider the cation fixation which reduces mobility. Cation exchange is very high in organic soils, like residual C&D material with wood fragments. Clays have a CEC rate between 5-60, where organic soils are greater than 200, meaning **cadmium is likely immobile in the monofill**. James Dragum, The Soil Chemistry of Hazardous Materials, 1988, pg 156. Cd has a low mobility (pg 178).

Chromium Loading from Leachfield

Mass balance inputs for concentrations from laboratory leaching. Calculations are based on ADEC mass balance model for septic leach fields.

$C_b := 86.9 \cdot \frac{\mu g}{l}$ Chromium concentration in background water supply (measured from monitoring well testing)

$C_{leach} := .2 \cdot \frac{mg}{l}$ Hypothetically assume Chromium leaches at the LOQ Level (Level of Quantification during leachate testing). No lab data exists to validate Chromium levels would ever reach this hypothetical level

$C_{infiltration} := 0 \cdot \frac{mg}{l}$ Chromium concentration in rainfall

Leach Field design inputs

$Q_{leach} := \frac{2.0 \cdot in \cdot 35 \cdot acre}{yr} = 5204 \ \frac{gal}{day}$ Monofill effluent (2.0 in / yr infiltration) * 35 acres. total area Two inches of infiltration is likely higher than expected (discussed in text portion of this report).

Aquifer characteristics

$k := 500 \cdot \frac{ft}{day}$ Hydraulic conductivity (based on J.A. Munter, Feb 2014 and aquifer testing by AS&G.

$b := 57 \cdot ft$ Aquifer thickness. This value is an average thickness based on modeling by Brailey Hydrologic Consultants; figure 4, layer 1, September 30, 2011. A larger thickness will create more dilution at the property boundary and lower concentrations.

$Width := \sqrt{35 \cdot acre} = 1235 \ ft$ width of existing leach field

$Area := Width \cdot b \cdot 1.5$ crossectional area of leach field * 1.5 to account for lateral dispersion and diffusion of sulfate in groundwater (following ADEC)

$Area = 105571 \ ft^2$ Cross sectional area of aquifer allowing for transverse dispersivity

$i := 0.008$ Gradient of aquifer, measured in July 2013.

Precipitation infiltration

$i_{infiltration} := \frac{2.0 \cdot in}{yr} = 0.0005 \ \frac{ft}{day}$ Weather records from both the Palmer Job Corps and the Alaska Extension Service show less than 1 inch of precipitation is available for infiltration. Refer to text for discussion.

$x := 50 \cdot ft$ Distance from source to receptor (property boundary)

$Area_{infiltration} := x \cdot Width$ Assumes infiltration between leach field and receptor provides infiltration to the underlying water-table aquifer

$Q := Area_{infiltration} \cdot i_{infiltration} = 211 \ \frac{gal}{day}$ Infiltration down gradient of monofill, between monofill and property boundary.

Results

$Q_b := k \cdot i \cdot Area = 422283 \ \frac{ft^2}{day}$

$$C_x := \frac{Q_b \cdot C_b + (Q_{leach} \cdot C_{leach}) + Q_i \cdot C_{infiltration}}{Q_b + Q_{leach} + Q_i} \qquad Zx$$

$C_x = 0.09 \ \frac{mg}{l}$ Chromium **concentration at nearest receptor** where $x = 50 \ ft$. The ADEC drinking water standard is 0.1 mg/l.

Iron Loading from Leachfield

Mass balance inputs for concentrations from laboratory leaching.
Calculations are based on ADEC mass balance model for septic leach fields.

$C_b := 76.4 \cdot \frac{mg}{l}$ Iron concentration in background water supply (measured from monitoring well testing)

$C_{leach} := 50 \cdot \frac{mg}{l}$ Hypothetically assume iron leaches at the LOQ Level (Level of Quantification during leachate testing). No lab data exists to validate iron levels would ever reach this hypothetical level

$C_{infiltration} := 0 \cdot \frac{mg}{l}$ iron concentration in rainfall

Leach Field design inputs

$Q_{leach} := \frac{2.0 \cdot in \cdot 35 \cdot acre}{yr} = 5204 \ \frac{gal}{day}$ Monofill effluent (2.0 in / yr infiltration) * 35 acres, total area. Two inches of infiltration is likely higher than expected (discussed in text portion of this report)

Aquifer characteristics

$k := 500 \cdot \frac{ft}{day}$ Hydraulic conductivity (based on J.A. Munter, Feb 2014 and aquifer testing by AS&G.

$b := 57 \cdot ft$ Aquifer thickness. This value is an average thickness based on modeling by Brailey Hydrologic Consultants, figure 4, layer 1, September 30, 2011. A larger thickness will create more dilution at the property boundary and lower concentrations.

$Width := \sqrt{35 \cdot acre} = 1235 \ ft$ width of existing leach field

$Area := Width \cdot b \cdot 1.5$ crossectional area of leach field * 1.5 to account for lateral dispersion and diffusion of sulfate in groundwater (following ADEC)

$Area = 105571 \ ft^2$ Cross sectional area of aquifer allowing for transverse dispersivity

$i := 0.008$ Gradient of aquifer, measured in July 2013, down gradient of ponds.

Precipitation infiltration

$i_{infiltration} := \frac{2 \cdot in}{yr} = (4.563 \cdot 10^{-4}) \ \frac{ft}{day}$ Weather records from both the Palmer Job Corps and the Alaska Extension Service show less than 1 inch of precipitation is available for infiltration. Refer to text for discussion.

$x := 50 \cdot ft$ Distance from source to receptor (property boundary)

$Area_{infiltration} := x \cdot Width$ Assumes infiltration between leach field and receptor provides infiltration to the underlying water-table aquifer

$Q_i := Area_{infiltration} \cdot i_{infiltration} = 211 \ \frac{gal}{day}$ Infiltration down gradient of monofill. between monofill and property boundary

Results

$Q_b := k \cdot i \cdot Area = 422283 \ \frac{ft^3}{day}$

$$C_T := \frac{Q_b \cdot C_b + (Q_{leach} \cdot C_{leach}) + Q_i \cdot C_{infiltration}}{Q_b + Q_{leach} + Q_i}$$

$C_T = 76.4 \ \frac{mg}{l}$

Iron concentration at nearest receptor where $x = 50 \ ft$. The ADEC secondary drinking water standard is 0.3 mg/l. Note that iron is already above the secondary drinking water limit in natural concentrations and that adding infiltration with a hypothetical concentration of 50 mg per liter has no increase in concentration at the property boundary.

Manganese Loading from Leach Field Model

Mass balance inputs for concentrations from laboratory leaching. Calculations are based on ADEC mass balance model for septic leach fields.

$C_b := 4386 \cdot \frac{\mu g}{l}$ Manganese concentration in background water supply (measured from monitoring well testing)

$C_{leach} := .384 \cdot \frac{mg}{l}$ Highest manganese concentration detected out of three laboratory leachate procedures. Actual on-site concentrations will be lower than this value because the soils are unsaturated, have minimal exposure to water and the laboratory saturated the samples for 18 hours

$C_{infiltration} := 0 \cdot \frac{mg}{l}$ Manganese concentration in rainfall

Leach Field design inputs

$Q_{leach} := \frac{2.0 \cdot in \cdot 35 \cdot acre}{yr} = 5204 \ \frac{gal}{day}$ Monofill effluent (2.0 in / yr infiltration) * 35 acres, total area Two inches of infiltration is likely higher than expected (discussed in text portion of this report)

Aquifer characteristics

$k := 500 \cdot \frac{ft}{day}$ Hydraulic conductivity (based on J A. Munter, Feb 2014 and aquifer testing by AS&G

$b := 57 \cdot ft$ Aquifer thickness. This value is an average thickness based on modeling by Brailey Hydrologic Consultants, figure 4, layer 1, September 30, 2011. A larger thickness will create more dilution at the property boundary and lower concentrations.

$Width := \sqrt{35 \cdot acre} = 1235 \ ft$ width of existing leach field

$Area := Width \cdot b \cdot 1.5$ crossectional area of leach field * 1.5 to account for lateral dispersion and diffusion of sulfate in groundwater (following ADEC)

$Area = 105571 \ ft^2$ Cross sectional area of aquifer allowing for transverse dispersivity

$i := 0.008$ Gradient of aquifer, measured in July 2013, downgradient of ponds.

Precipitation infiltration

$i_{infiltration} := \frac{2 \cdot in}{yr} = (4.563 \cdot 10^{-4}) \ \frac{ft}{day}$ Weather records from both the Palmer Job Corps and the Alaska Extension Service show less than 1 inch of precipitation is available for infiltration. Refer to text for discussion.

$x := 50 \cdot ft$ Distance from source to receptor (property boundary)

$Area_{infiltration} := x \cdot Width$ Assumes infiltration between leach field and receptor provides infiltration to the underlying water-table aquifer

$Q_i := Area_{infiltration} \cdot i_{infiltration} = 211 \ \frac{gal}{day}$ Infiltration down gradient of monofill, between monofill and property boundary.

Results

$Q_b := k \cdot i \cdot Area = 422283 \ \frac{ft^3}{day}$

$$C_x := \frac{Q_b \cdot C_b + (Q_{leach} \cdot C_{leach}) + Q_i \cdot C_{infiltration}}{Q_b + Q_{leach} + Q_i}$$

$C_x = 4.3791 \ \frac{mg}{l}$

Manganese concentration at nearest receptor where $x = 50 \ ft$. The ADEC drinking water standard is 0.05 mg/l. Note that manganese is already above the drinking water limit in natural concentrations and that adding infiltration actually dilutes manganese at the compliance point, the property boundary.

Sulfate Loading from Leachfield

Mass balance inputs for concentrations from laboratory leaching. Calculations are based on ADEC mass balance model for septic leach fields.

$C_b := 47.1 \cdot \frac{mg}{l}$

Sulfate concentration in background water supply (measured from monitoring well testing)

$C_{leach} := 200 \cdot \frac{mg}{l}$

Sulfate concentration below monofill (assumed). Laboratory proceedures for leaching produced concentrations as high as 673 mg/l. The process saturated the residual waste sample for 18 hours and added acid to increase the leaching. The monofil will be in an unsaturated soil, without the addition of acid. Thus, leaching is not expected For the purpoose of modeling, we assume that 200 mg/l could leach. This concentration is much higher than what is expected.

$C_{infiltration} := 0 \cdot \frac{mg}{l}$

Sulfate concentration in rainfall

Leach Field design inputs

$Q_{leach} := \frac{2 \cdot in \cdot 35 \cdot acre}{yr} = 5204 \ \frac{gal}{day}$

Monofill effluent (2.0 in / yr infiltration) * 35 acres, total area. Two inches of infiltration is likely higher than expected (discussed in text portion of this report)

Aquifer characteristics

$k := 500 \cdot \frac{ft}{day}$

Hydraulic conductivity (based on J.A. Munter, Feb 2014, and aquifer testing by AS&G.

$b := 57 \cdot ft$

Aquifer thickness. This value is an average thickness based on modeling by Brailey Hydrologic Consultants, figure 4, layer 1, September 30, 2011. A larger thickness will create more dilution at the property boundary and lower concentrations.

$Width := \sqrt{35 \cdot acre} = 1235 \ ft$

width of existing leach field

$Area := Width \cdot b \cdot 1.5$

crossectional area of leach field * 1.5 to account for lateral dispersion and diffusion of sulfate in groundwater (following ADEC)

$Area = 105571 \ ft^2$

Cross sectional area of aquifer allowing for transverse dispersivity

$i := 0.008$

Gradient of aquifer, down gradient of the ponds, measured in July 2013.

Precipitation infiltration

$i_{infiltration} := \frac{2 \cdot in}{yr} = (4.563 \cdot 10^{-4}) \ \frac{ft}{day}$

Weather records from both the Palmer Job Corps and the Alaska Extension Service show less than 1 inch of precipitation is available for infiltration. Refer to text for discussion.

$x := 50 \cdot ft$

Distance from source to receptor (property boundary)

$Area_{infiltration} := x \cdot Width$

Assumes infiltration between leach field and receptor provides infiltration to the underlying water-table aquifer

$Q_i := Area_{infiltration} \cdot i_{infiltration} = 211 \ \frac{gal}{day}$

Results

$Q_h := k \cdot i \cdot Area = 422283 \ \frac{ft^3}{day}$

$$C_x := \frac{Q_h \cdot C_b + (Q_{leach} \cdot C_{leach}) + Q_i \cdot C_{infiltration}}{Q_h + Q_{leach} + Q_i}$$

$C_x = 47.3 \ \frac{mg}{l}$

Sulfate concentration at nearest receptor where $x = 50 \ ft$. This is an increase of 0.2 mg/l over the background concentration of 47.1 mg/l. The ADCE drinking water standard is 250 mg/l.

Pentachlorophenol Loading from Leachfield

Mass balance inputs for concentrations from laboratory leaching. Calculations are based on ADEC mass balance model for septic leach fields.

$C_b := 0 \cdot \frac{mg}{l}$ — Pentachlorophenol concentration in background water supply (measured from monitoring well testing)

$C_{leach} := .61 \cdot \frac{mg}{l}$ — Pentachlorophenol Limit of Quantification for laboratory leachate proceedures. Actual on-site concentrations will be lower than this value because the soils are unsaturated and the laboratory saturated the samples for 18 hours

$C_{infiltration} := 0 \cdot \frac{mg}{l}$ — Pentachlorophenol concentration in rainfall

Leach Field design inputs

$Q_{leach} := \frac{2.0 \cdot in \cdot 35 \cdot acre}{yr} = 5204 \ \frac{gal}{day}$ — Monofill effluent (3.03 in / yr infiltration) * 35 acres, total area. Two inches of infiltration is likely higher than expected (discussed in text portion of this report).

Aquifer characteristics

$k := 500 \cdot \frac{ft}{day}$ — Hydraulic conductivity (based on J.A. Munter, Feb 2014 and aquifer testing by AS&G.

$b := 57 \cdot ft$ — Aquifer thickness. This value is an average thickness based on modeling by Bralley Hydrologic Consultants, figure 4, layer 1, September 30, 2011. A larger thickness will create more dilution at the property boundary and lower concentrations.

$Width := \sqrt{35 \cdot acre} = 1235 \ ft$ — width of existing leach field

$Area := Width \cdot b \cdot 1.5$ — crossectional area of leach field * 1.5 to account for lateral dispersion and diffusion of sulfate in groundwater (following ADEC)

$Area = 105571 \ ft^2$ — Cross sectional area of aquifer allowing for transverse dispersivity

$i := 0.008$ — Gradient of aquifer, down gradient of the ponds, measured in July 2013.

Precipitation infiltration

$i_{infiltration} := \frac{2 \cdot in}{yr} = (4.563 \cdot 10^{-4}) \ \frac{ft}{day}$ — Weather records from both the Palmer Job Corps and the Alaska Extension Service show less than 1 inch of precipitation is available for infiltration. Refer to text for discussion.

$x := 50 \cdot ft$ — Distance from source to receptor (property boundary)

$Area_{infiltration} := x \cdot Width$ — Assumes infiltration between leach field and receptor provides infiltration to the underlying water-table aquifer

$Q_i := Area_{infiltration} \cdot i_{infiltration} = 211 \ \frac{gal}{day}$ — Infiltration down gradient of monofill, between monofill and property boundary.

Results

$Q_b := k \cdot i \cdot Area = 422283 \ \frac{ft^3}{day}$

$$C_x := \frac{Q_b \cdot C_b + (Q_{leach} \cdot C_{leach}) + Q_i \cdot C_{infiltration}}{Q_b + Q_{leach} + Q_i}$$

$C_x = 1 \ \frac{\mu g}{l}$

Pentachlorophenol concentration at nearest receptor where $x = 50 \ ft$. The ADEC drinking water standard is 1 μg/l. The receptor is the property boundary. (Partitioning processes, including adsorption and biological degredation would reduce this concentration to less than shown). Therefore, if Pentachlorophenol is present at the LOQ, ADEC compliance concentrations could be exceeded, ignoring partitioning processes and biodegredation. (see next page for discussion of partitioning processes).

Partitioning of Pentachlorophenol between solid and liquid and retardation factor in groundwater

Variables:

$Conc := 1 \cdot \frac{\mu g}{L}$ Contaminant concentration, hypothetical, assumed LOQ from leaching test results, after migrating through the monofill (see previous page).

$\phi := 28\%$ Porosity (%), estimated for hydraulic conductivity of 1.4* 10 ^-2 cm/s

$Carbon := .23$ Carbon fraction (%), measured by Terra Firma

$\rho_b := .803 \cdot \frac{gm}{cm^3}$ Soil bulk density of residual waste, compacted. Terra Firma

$Vol := 1 \cdot L$ Volume (litre)

$K_{oc} := (1.115 \cdot 10^3) \frac{l}{kg}$ US EPA, 1996, Soil Screening Guidance: Technical Background Document, 2nd Edition. Page C-5, pH=6.2, which is water pH in local Palmer groundwater.

Partioning coefficient

$K_d := K_{oc} \cdot Carbon = 256.45 \frac{l}{kg}$ Liquid *concentration*

$X := K_d \cdot Conc = 2.565 \cdot 10^{-7}$ *Sorbed· soil· concentration*, mg/kg

$M_s := X \cdot Vol \cdot \rho_b = (2.059 \cdot 10^{-4})\ gm$ Mass in soil

$M_l := Conc \cdot Vol \cdot \phi = (2.8 \cdot 10^{-7})\ gm$ Mass in Liquid

$\%liquid := \frac{M_l \cdot 100}{M_s + M_l} = 0.136$ Percentage of total contaminant mass in aqueous phase

$R := 1 + \frac{\rho_b \cdot (K_d)}{\phi} = 736$ Retardation factor (this substance is slightly mobile in this environment). One molecule would require 70 years to travel 500 feet, assuming no biodegradation occurs within 70 years.

$\%liquid \cdot Conc = 0.1 \frac{\mu g}{l}$ Final concentration of Pentachlorophenol after leaching with two inches of infiltration. ADEC MCL is 1.0 $\frac{\mu g}{l}$. Actual value would be less because less infiltration is available.

Re: **Response to MSB's Information Request; CMS Conditional Use Permit (CUP)**

At your request, I have researched the issues regarding the proposed Central Monofill Services (CMS) monofill and prepared this response. There has been considerable conflicting information presented. While professionals in DEC and other jurisdictions familiar with the type of screening, recycling, and monofill proposed may concur the risks are sufficiently low, MSB staff, potentially impacted neighbors, and friends need more information to resolve apparent conflicts. I am glad you agreed to comply with their request.

To prepare this response, I reviewed the submittals, replies, comments, and rebuttals in the MSB CUP record, their referenced documents, studies of risks and management of construction and demolition (C&D) landfills, and local hydrological and soils studies, including conversations with the authors. New investigations included examining historical groundwater monitoring data for seven select local wells and correlating to precipitation and the Matanuska River, correlating leachate collection at the MSB Central Landfill with precipitation and established models, and determining the timing of recent groundwater level maxima.

Our Dumps and Landfills, Past and Future:

To envision where we're going, we should review our past:

- Until the late 60's, we threw garbage, autos, railcars, whatever, over the bluff to the Matanuska R. Sometimes we'd burn it first; no oversight, anything goes[i].
- Barney Anderson and son Dale had a local garbage pickup service and dump located on his property north of and adjacent to the proposed monofill[ii]. Owner oversight and limited access helped exclude disposals of what we now recognize as potentially hazardous waste, and regular burning limited the total volume.
- In 1976, EPA's RCRA hazardous waste regulations became law and we slowly reduced the amount we used and threw away. Increased expense of legally disposing hazardous wastes put pressure on unmonitored landfills, such as at the Butte and Big Lake.
- MSB opened the central landfill (CLF) in 1980[iii]; all waste was put in an unlined pit with moderate oversight. By the early 90's, programs were in place to collect household and conditionally exempt hazardous wastes. Individual loads at the scale house or transfer stations are rarely inspected. Downgradient monitoring wells were installed in 1993.
- Recent CLF groundwater monitoring[iv] shows several parameters statistically exceed background, mostly chlorinated solvents and fuel constituents. No concentrations currently exceed site groundwater protection standards.
- In 2004, the first lined cell at the CLF opened, with additional cells in 2008 and 2010.

- The huge costs of building and operating lined cells prompted CLF to divert inert wastes of various categories to an unlined C&D cell, which has no directly downgradient monitoring wells. The consumer characterizes each load with limited inspection by the MSB. Side streams include appliances and large metal pieces.
- Alaska Demolition opened a C&D monofill in Palmer in 2004; no liner or monitoring wells were required. Waste characterizations primarily rely on pre-demolition surveys to remove hazards, and jobsite salvage of large components is promoted.

The MSB C&D cell and lined mixed waste cells are rapidly reaching capacity; bids for planning new cells, closing existing cells, and managing leachate were solicited this year. The much larger Alaska Demolition monofill has seven years remaining. Another C&D monofill will come to the valley soon, whether at the proposed site or elsewhere. We should expect it to be a step forward, while extending the life of the CLF for disposal of mixed domestic and unsorted wastes.

The importance of intensive recycling and processing should not be underestimated. The close inspection and segregation of small portions, necessary for maximum recycling value, removes for proper disposal far more incompatible wastes than bulk handling can. This results from a combination of management policies, such as routine demolition site inspections and developing suitable recycling and disposal categories. The multiple inspection/removal processes, followed by handpicking on a conveyor line, is highly effective. It is also more flexible, enabling easy addition of segregation categories as materials, markets, and regulations change.

Shredding residue remaining after removing side streams provides structural uniformity enabling more precise and durable cell caps that can more readily shed water to percolation basins. A more stable final cover enables higher value end uses, increasing the owners' commitment.

Important features of the CMS proposal compared to older C&D monofill systems include:

- The superior ability of the recycling process to identify and segregate materials not suitable for placing in the monofill, need special treatment, or for cost recovery.
- Greater flexibility to adapt to new wastes, regulations, and market conditions.
- Processing provides more uniform and stable material, enabling enhanced runoff control during lift construction and final cap.
- Overall, the recycling and processing system lowers monofill life cycle risks and provides a more usable and valuable end product.

Impacts to Drinking Water (see Appendix 1):

The CUP application stated "*...monofill will not present a threat to groundwater...*" Such absolute statements are no more defensible than "*this landfill will generate toxic leachate that you will drink*". MSB staff needs more local evidence to sort out the conflicting claims.

The root of the controversy is the annual precipitation contribution to groundwater at the site, from which potential impacts of leachate can be calculated and mitigated. Mr. Munter stated[v]:

"There is significant annual precipitation in the Palmer area. It is sufficient to support mature deciduous and coniferous forest, hundreds if not thousands of household water supply-wells, numerous municipal and irrigation wells, non-irrigated agriculture..."

To investigate this claim and provide details of nature and quantities of groundwater recharge from precipitation, I performed the research described in Appendix 1. Summary results include:

- Elevated bedrock under the city of Palmer prevents groundwater recharge from the Matanuska R.; recharge from precipitation is inadequate to support productive wells.

- For the area south of Palmer, detailed local studies and data show inflow from the Matanuska R. is the primary source of the abundant groundwater, which flows southwest from near the airport, under the Springer Rd. area, and into the river floodplain south of the monofill site.

- A regional groundwater investigation prepared for the MSB in 1991, co-authored by Munter with no fieldwork, mistakenly showed groundwater south of Palmer flowing southeast towards the river. This study appears to be the major source of groundwater controversy.

- Extensive climate and soils studies for the valley note a precipitation deficit in the Springer Rd. area, which increases to a precipitation surplus further west in the valley and at higher elevations. A similar study noted that groundwater recharge from precipitation followed a similar pattern, indicating the proposed site has approximately 1.4 inches/year recharge.

- I researched well level monitoring data and compared it to precipitation and Matanuska R. flood stage. This allowed comparisons of influences from the Matanuska R. and precipitation events (i.e., long term, prior season, fall peaks, and run-on) on each well. I selected seven wells near the proposed site and the period from 1956-1965, as the most complete and reliable data sets, each having 1-5 records per month. I confirmed locations and features with property owners, and visited the sites. For each well series, I tried to identify patterns or anomalies with a water level rise of 1 ft or more above the background noise, then compared them to the corresponding or prior precipitation (monthly or annual) and the Matanuska R. flow. Observations include:
  - The wells showed varied water level responses to monthly or annual precipitation and to seasons, as well as different responses in co-located aquifers.
  - Woods' north well rose and fell within one month of the Matanuska flood stages, indicating the river is the primary groundwater source east of the monofill site.
  - Winter and spring runoff collected in depressions upgradient of three of the wells was the presumed cause of the great majority of distinct level rises.
  - The non-responsiveness to seasonal precipitation shown by the deep wells indicates recharge occurred long ago (as indicated by isotope analyses) and in the distant slopes and foothills, which have far greater precipitation and percolation.
  - The high correlation between proximity to catch basins and groundwater recharge indicates the importance of runoff. These wells were (are still) in primarily agricultural settings, cleared, level to hilly, planted with hay or other crops, and designed to retain moisture to the extent possible to minimize irrigation needs.

- The effects of the 1964 earthquake on well water levels are also described in Appendix 1:
  - The wells varied from no visible response, to rising 30 ft or falling 23 ft the day of the earthquake and recovering all or most within a couple months. One well fell 23 ft then began recovery before the earthquake.
  - There are no known reports of the 1964 earthquake on the area's groundwater, and the USGS hydrology department was unaware of this data.

- I cannot detect any long term groundwater changes attributable to the earthquake.

- I investigated leachate generation at the CLF and compared conditions with the proposed monofill to estimate percolation under similar and alternate design goals. Methods and data are presented in Appendix 1 and summary results include:
  - Percolation for the CLF apparently validated the Deep Percolation Model for the CLF location near the upper edge of the 1.5-4 inches/yr groundwater recharge zone.
  - The proposed monofill location is at the upper edge of the 0-1.4 inches/yr zone.
  - CLF cells have very porous gravel surface; monofill lift and final caps designed to shed water can reduce the percolation below the modeled 1.4 in/yr.

- I researched various sources to determine the current groundwater levels at the proposed monofill site compared to historical levels in nearby aquifers. All sources indicate 2013 to early 2014 had very high groundwater, and some sources indicate this period had the highest levels in 35 years of observation. This provides greater confidence for designing the monofill base.

Reply to Comments:

I investigated the comments by MSB staff provided on 2/13/14; except for #s 1 and 25, I concur with staff these are valid requests for clarification, which I expect will be in CMS's response.

MSB staff requested you address issues raised in the J. A. Munter Consulting, Inc. review of 2/7/14 (MSB comments #s 1 and 25). I have investigated and sorted them into related issues.

- Hydrology and groundwater recharge:

  The multiple lines of evidence from many diverse sources presented in Appendix 1 and summarized above disputes Munter's fundamental conjecture that the abundant groundwater is produced by local precipitation. Overlooking the Matanuska River's recharge contribution and attributing it instead to local precipitation severely jeopardizes his subsequent groundwater or percolation conjectures.

  Another significant oversight is not recognizing the importance of runoff for groundwater recharge in the catch basins and percolation reduction elsewhere.

- Comparative references:

  The studies he referenced are outdated, but highlight design and O&M deficiencies corrected by latest generation C&D monofills. The 1995 study included mixed waste and pre-RCRA disposals. The 2009 Ohio study included a variety of landfills, many accepting out-of-state pulverized loads with different definitions of C&D materials or procedures, if any, for pre-screening, segregation, or recycling. This waste was placed in uncapped lined pits where leachate in extended contact with waste was often recirculated. These wet pits often became festering anoxic stews in hot weather, and are good examples of bad designs.

  Munter did not attempt to compare the proposed monofill design and O&M with standards of the many other states that allow modern C&D monofills without liners. These states typically have stringent requirements for screening with multiple subcategories of C&D permits

depending on materials allowed and siting. The proposed monofill operation would apparently be welcome in these states, too, especially as the proposed screening segregates most of the gypsum and the cell construction reduces the already low percolation.

- Fate and effect modeling:

As previously described, I do not agree with Munter's basic assumptions of local groundwater source or precipitation recharge. He offers no empirical basis for his comments regarding modeling, calculations of percolation, runoff, or groundwater transport.

I do agree with Munter that the contaminant fate and transport model example used by Maddox & Associates (M&A) could be improved. Simple 2D models that do not account for the complex attenuation of mixtures often overestimate distance traveled and time to naturally attenuate by orders of magnitude. They should be used only to show a particular risk is *de minimis*, but not to quantify its magnitude or spatial extent. For instance, a large diesel spill could result in a groundwater plume with several times the benzene concentration M&A modeled, but there are apparently no diesel spills with a groundwater plume anywhere close to a mile long in the DEC contaminated sites database[vi]. A 4-phase model[vii] would be more useful, but only after calibrating inputs to site conditions. PCE and DCA were common pre-RCRA chlorinated solvents, closely regulated now, and easily screened out along with other liquids. A more meaningful exercise would model more common C&D constituents, such as sulfate.

- Health risk characterization:

Munter makes a convincing case that C&D waste can present health risks; that should only be the first step in developing a conceptual site model (CSM). Assessing and quantifying these risks is necessary in order to control and reduce them. Any CSM is continuously updated through design, construction, monitoring, closure, and post-closure. Unlike the contaminated sites program guidance Munter cited, the facility CSM is intended to first prevent risks to human health, with contingencies to mitigate design or O&M mishaps.

Health risk characterization and mitigation steps include:

- Exclusion of inappropriate wastes: Industry and regulators have developed (and continuously update) a long list of wastes to exclude. Regulatory programs, pre-demolition assessments, operator training, and tools to identify specific wastes help avoid those problematic wastes, while assessment tools such as SPLP provide feedback of effectiveness, and lead to process/assessment modifications if needed.
- Precipitation percolates through the cell, then through the minimum 10 ft silty soil buffer where some of the dissolved substances are removed and some reach groundwater. As with septic systems, leachate concentrations when exiting the monofill or first meeting groundwater do not indicate a threshold health risk.
- Between the cell and the monitoring wells, leachate constituents will be adsorbed, degraded, and diluted. Typically, constituents will be compared to groundwater protection standards, and mitigation and/or further assessment implemented as required by DEC to prevent health impacts to receptors.
- If human health impacts appear likely, providing water from the city main running along the highway places an easily implemented upper bound on health risks.

Summary:

Based on these investigations, I believe the proposed monofill will not cause recognized adverse health impacts from contamination of groundwater. There appears to be robust groundwater at the site primarily supplied from the Matanuska R. and the Talkeetna Mtn. foothills. The estimated 1.4 inches/yr recharge from precipitation in this area is a minor contribution.

The recycling and material processing system enables more confident risk reduction through enhanced inspection, and more precise monofill construction allowing cell design to increase runoff and end use value. Taken together, the low local groundwater recharge from precipitation coupled with the proposed recycling and monofill system effectively reduce the major health risk, contamination of drinking water. I presume clarifications and the other potential problems raised by MSB staff will be addressed in CMS's response.

There is no perfect industrial location or way to eliminate risks. Here, area climate reduces groundwater risks. The CMS system appears to be superior to other current C&D monofill systems for its ability to further reduce life cycle health risks and enhance end use value.

Please call me if you have any questions about this report.

Sincerely,

Ralph Hulbert

Ralph Hulbert, P.E.

Appendix 1
Infiltration, Percolation, and Groundwater Recharge near Palmer

This study examines the relationship between precipitation and groundwater recharge in the area south and west of Palmer pertinent to the monofill proposed by CMS. Sources include large and small-scale hydrological studies, climate data, long time residents, and previously unpublished data compilations. This information is intended to help land use planners and developers resolve conflicts and better assess and mitigate risks to drinking water.

1. Area-wide Factors

A well may tap groundwater that fell as precipitation recently nearby or decades ago and far away. The high production wells south of Palmer tap groundwater that recently came from the Matanuska River, which fell as rain and snow on distant mountains and glaciers. Wells further west tap aquifers primarily recharged by precipitation that fell several years ago in the upper Wasilla Cr. drainage. Amount of groundwater recharged by local precipitation varies by region, smaller scale drainage features, and type of engineered surface.

Assessing and mitigating potential health risks from contaminants leaching from the monofill requires careful evaluation of the following processes:

Precipitation:

There are three nearby weather stations currently listed by NOAA[i], with data also available from the Western Regional Climate Center[ii] (see Figure 1 for current locations):

- "Experiment Farm", id505733, (Matanuska AES); the 1922-2013 precipitation average is 15.27 inches, and the 2004-2013 precipitation average is 14.97 inches.
- "Job Corp", id506870, (Palmer AAES, various locations); the 1948-2013 precipitation average is 15.73 inches, and the 2004-2013 average is 18.19 inches.
- "Palmer Airport", id506867, ~1/2 mile from Job Corp, has been collecting data since 2002. The 9-year precipitation average is 10.91 inches.

The large variation in recent annual precipitation between nearby sites merits examination. Precipitation increases with elevation, but this would not explain the difference between the Airport and Job Corps sites. The state climatologist[iii] suggests the Airport's exposed location contributes to under-measuring precipitation. Rain or snow will fall more in the lees than on the windswept areas. November 2010 was windy and wet; the Airport reported wind every day, 14 days with gusts >20 mph, 18 days with rain or snow, but only measured 0.62 inches of precipitation. Meanwhile, the Job Corps station (more sheltered) measured 11.04 inches and the Experiment Farm (moderate exposure) measured 1.68 inches. The proposed monofill site is slightly lower elevation and exposed to wind, indicating more similarity to the Experiment Farm and the Airport.

Infiltration and Percolation:

Soil scientists' distinction of infiltration from percolation: "The downward entry of water into the immediate surface of soil or other material; as contrasted with percolation, which is movement of water through soil layers or material… The rate can be limited by the infiltration capacity of the soil or the rate at which water is applied at the surface[iv]."

Low permeability or frozen soils have low infiltration rates. Precipitation exceeding the infiltration rate will either remain at the surface or run off. Once water has entered the soil and saturated a particular soil stratum, water will percolate through that stratum at a rate determined by the effective permeability. When a deeper stratum of lower permeability (aquitard) is encountered, the process repeats.

Runoff and Run-on:

These factors are controlled by topography and surface type, and determine locations of groundwater recharge. The largest runoff factor is whether soil is frozen. Winter Chinooks routinely exceed storm drain and ditch capacities, fill depressions, and leave fields bare (see Photos). Runoff is less during the growing season when vegetation or forest mulch slows runoff allowing more evapotranspiration and infiltration.

Managing precipitation is a mature science; agriculture, road building, city design, and landfills may have different goals and practices, but use the same fundamentals. Each project has to design for the predicted precipitation patterns, runoff pathways, and destinations.

Evapotranspiration:

Water in the soil is lost to the atmosphere by evaporation from the surface and transpiration by plant uptake and vapor transport from deeper strata. Taken together, evapotranspiration returns most of the annual precipitation back to the atmosphere. The NRCS chief soil scientist[v] described the Palmer terrace as having a measured average annual deficit of 4 inches of precipitation, while the soil moisture balance becomes increasingly positive with higher precipitation to the north and west. The net precipitation deficit generally applies to a "fully vegetated land surface abundantly supplied with water".

Evapotranspiration models are based on landforms, temperature, and precipitation averages for an area. A large factor in evapotranspiration is wind, especially the spring and summer Knik winds, but is not well documented or included in the interpolative models. Figures 2 and 3 show Matanuska and Knik wind frequencies respectively[vi].

Groundwater Recharge:

Precipitation that does not run off or return to the atmosphere percolates through the soil and recharges groundwater. Figure 4 shows predicted annual groundwater recharge in the core area[vii]. The report author[viii] described the regional scale model used inputs from the NRCS Soil Survey, but not wind. In general, this figure corresponds to NRCS' Soil Survey that measured precipitation deficits in the Palmer terrace and surpluses at higher elevations.

Figure 4 indicates the MSB Central Landfill is near the upper edge of the 1.5-4 inch recharge, while the proposed monofill is at the upper edge of the 0-1.4 inch zone.

Groundwater can still be recharged by precipitation in areas with net deficits. Runoff will exacerbate precipitation deficit from runoff areas, but cause recharge in the catch basins. Short-term elevation rises of the groundwater can be observed in wells near the basins.

Precipitation recharge of 0-1.4 inches in the Palmer terrace can not account for the very high groundwater withdrawals, which include city wells, high irrigation consumption, and outflow streams south of the terrace. There is a simple explanation.

2. Hydrology Studies

Despite several hydrology studies in the proposed monofill area, disagreement remains regarding aquifers, flow directions, and sources of groundwater, especially under the Palmer terrace (Springer Rd. system). Multiple lines of evidence are provided below.

History of Major Discrepancies

USGS under Frank Trainer compiled the first comprehensive Palmer area hydrology studies, starting in the late 1940's. These included interviews with homesteaders and well drillers to locate and describe all the known wells, the forerunner of WELTS[ix]. USGS then began regular water level monitoring in numerous wells and the Matanuska River east of Palmer. After two years of draught and two of high precipitation, Trainer[x] provided observations of two wells near the site:

> "Water-level recovery is most complete in the Woods well; this well is on the extensive terrace south of Palmer, where the water table is controlled by the Matanuska River.
>
> Data for the Linn well, … suggest slight recovery during the late spring of 1950 before further decline. Each well shows partial recovery during the summer of 1951.
>
> The Linn well is on a hill but the ground-water level is probably controlled by the water table beneath the alluvial flat west of Matanuska; hence the water-level fluctuation in the Linn well, like that in the Woods well, is relatively slight.
>
> The rapid decline and slow recovery of ground-water levels, as shown by these data, suggest that annual additions to the groundwater body represent only a small proportion of the annual precipitation received in the agricultural area"

A subsequent USGS report[xi] described the relatively flat Palmer terrace as recent glacial outwash. The southern terrace receives much of its recharge from the Matanuska R. with wells in thick sandy gravel potentially suitable for irrigation. The northeastern terrace overlays shallow bedrock and till with no river recharge, resulting in mostly inadequate wells. The area west of the Palmer terrace is described as irregular and complex mixtures of glacial

till ("hardpan") overlaid by or including layers of gravel outwash. Wells are sometimes constructed in shallow unconfined perched aquifers, but deeper wells often tap confined or artesian aquifers, especially the higher producers (city wells #1 & 3 on Scott Rd.).

A borough sponsored regional groundwater study[xii], prepared by J. Jokela, James Munter, and James Evans in 1991, used surface water body elevations and well drillers' logs to plot groundwater contours. There was no fieldwork or apparent attempt to check if the wells tapped the same aquifer. This study grouped the Palmer terrace with Lazy Mt., presuming the source of groundwater at both locations is local precipitation. Flow directions were drawn toward the Matanuska R., southeast in the southern Palmer terrace (as marked on Figure 1), ignoring Trainer's observations. This mistake is far more than missing a local groundwater flow direction by 90°; this area has very productive wells for irrigation and city supply, and identifying its groundwater source is critical. If groundwater flows southeast, its source must be extremely high local precipitation recharge (absent in adjacent areas), while a southwest flow with the Matanuska R. as the source explains the abundance.

Published Smaller Scale Hydrological Studies:

Additional hydrological studies help clarify groundwater sources and flow directions. Locations of these studies are shown on Figure 1.

- The MSB Central Landfill has performed quarterly groundwater monitoring since 1986, currently monitoring 14 wells on a rotating basis. These are constructed in the unconfined aquifer of 3-67 ft thickness in highly permeable sands and gravel; groundwater flow direction is due south. Background arsenic concentration was 0.11 mg/l (drinking water Maximum Contaminant Levels are 0.01 mg/l). This aquifer lies on confining silt/clay layer 45-100+ ft thick. Most neighboring domestic wells draw from a deeper confined aquifer[xiii]. Figure 5 shows the contour map.

- The City of Palmer needed more water than was available from city wells #1-3 west of town, which draw from artesian aquifers, the deepest at 660 ft. Well #4 was then located south of Palmer in an unconfined aquifer at 103 ft, ~40 ft below the level of the Matanuska to the east. The 1200 gpm flow rate was limited by pump capacity. TERRASAT[xiv] mapped the bedrock under the city, confirming that it limited groundwater recharge in the city core (northern terrace). Bedrock was at 180 ft under well #4, allowing river recharge. Concurrent level measurements from nine wells showed flow was west-southwest (see Figure 6). Well #5 was drilled next to #4 with similar high productivity.

- The City of Palmer mapped groundwater[xv] near the wastewater treatment plant where groundwater from the southern terrace re-enters the Matanuska floodplain. Figure 7 shows groundwater flowing to the southwest. Robust springs occur along the bluff, coalescing into several streams winding southwest across the currently abandoned floodplain. The WWTP discharges to a stream that has a mean flow of 11.9 million gallons per day[xvi] after collecting water from only 3300 ft along the bluff. These consistent springs support huge spawning salmon returns; the 6-year average of 8763 counted spawners[xvii] in this stream exceeds Wasilla Cr. or any other Matanuska tributary.

- Extensive groundwater modeling conducted at the Anchorage Sand and Gravel[xviii] pit found that groundwater just north of the proposed monofill was recharged both from higher elevations to the north and from the Matanuska (Palmer terrace). A defining feature is a bedrock dike separating High Ridge and Baird lakes from Canoe and Irene lakes. This bedrock also limited the westward erosion of the ancient crevasse-moraine system by the more recent Matanuska R. Figure 8 shows groundwater contours indicating southeast flow, which then curves southwest around the bedrock.

- Environmental Management, Inc. and TERRASAT are currently monitoring the area around the proposed monofill, and their final reports have not been reviewed.

- Isotopic analyses of groundwater allow calculation of its apparent age (time since it fell as precipitation) and relation to other groundwater. Roy Glass[xix] tested groundwater from 16 wells in the valley, including city well #4 and Woods' north well, both in the southern Palmer terrace; water ages were 0.3 and 0.8 years respectively, by far the youngest of any wells sampled and consistent with river recharge. Wells north and west of the Palmer terrace had groundwater ages from 13 to 27 years, indicating a long travel time from the upland sources with little dilution from fresh precipitation.

These smaller scale studies reinforce Trainer's concept of the southern Palmer terrace recharged primarily from the Matanuska while the hilly terrain to the west is recharged from precipitation falling at higher elevations to the north. However, more information is needed to quantify relative contributions of precipitation to groundwater at the monofill scale.

Well Level Responses to Precipitation, Runoff, and River Flooding:

I researched historical USGS well monitoring data[xx], and compared fluctuations in levels to precipitation and Matanuska R. flood stages[xxi]. This allowed comparisons of influences from the Matanuska R. and precipitation events (i.e., long term, prior season, fall peaks, and run-on) for each well, from which I hoped to ascertain influences on recharge.

The seven wells selected (shown on Figure 1 and Photos) and the period from 1956-1965, appeared to be the most complete and reliable long-term data sets, each having 1-5 records per month. I confirmed locations and features with property owners[xxii] and DNR[xxiii], reviewed historical aerial photos, examined the well logs[xxiv], and visited the sites.

Figure 9 is an Excel generated chart showing the well levels, monthly precipitation, and Matanuska R. flood stage for the 1956-1965 period. Well level fluctuations and seasonal relationships were examined. In order to include data on a single chart, each well series was shown at an arbitrary datum above sea level (i.e., groundwater level -100 ft). Precipitation from the Palmer AAES (Job Corp) station is shown in inches times five. The Matanuska river flow was used, since the gauge level was not reported for several years, and shown in 1000s cubic feet per second, with zero floe offset on the chart to base 30.

For each well series, patterns or anomalies with a water level rise of 1 ft or more above the background noise were compared to the corresponding precipitation (prior or current monthly) and the Matanuska R. flow. Each anomalous water level fluctuation was tagged according to season when the rise began, to irrigation, or Matanuska, if clear. The wells showed varied water level responses to monthly or annual precipitation and to seasons, including different aquifers at the same location. Characteristics of individual wells were then analyzed:

- Woods' north well was in a flat field with no nearby depressions, 83 ft deep, finished in coarse sand and gravel. Levels rose 1-3 ft each of the ten years, beginning the rise, cresting, and falling within one month of similar stages of the Matanuska flooding. The summer precipitation was not as similar in timing and magnitude. There were two milder winter and one spring rises. Isotopic analyses showed this was Matanuska R. water.

- Woods' south well was located in a field on the edge of a depression where runoff from nearby fields still collects. It was drilled through sandy clay (glacial till) into bedrock at 264-282 ft and screened at 109 ft in a thin layer of gravel with sand. This till apparently restricted lateral recharge from the Matanuska, resulting in a greater influence from local recharge. There were five rises that occurred in winter, three in spring and four in fall; all of these occurred at times unlikely to have crops in the fields and when runoff was more likely. The highest rises were in winter, presumably from snowmelt.

- Linn's well is adjacent to a depression in an area of rolling hills, 108 ft deep. Rises occurred three times in spring, once in winter, and twice in fall.

- Three wells (NW Exp Farm wells 1-3) were co-located in a single well house at the edge of a field below a bluff, drilled to 295, 259, and 313 ft respectively, each apparently drawing from different aquifers. The deeper two wells usually showed a level decrease when the other was used for irrigation, and showed parallel increases twice in spring and once in fall, with the deeper well lagging by almost a month. Five events showed no correlation between wells. The shallow well #2 was artesian, with approximately 10 ft higher water level than the other two wells; it showed barely perceptible flutter when the deeper wells were pumping for irrigation, but no apparent response to seasonal precipitation. This well showed a gradual variation of ~1.5 ft over periods of about 8-13 years (extended series to 1993), while wells #1 and #3 had periods of about six years.

- Another well (SE Exp Farm) in the same field, but closer to upgradient catch basins, was hand dug to 40 ft. It had only minor variations, with two spring and three winter rises.

Summary observations regarding well groundwater level fluctuations from this data include:

- The correlation of level fluctuation with river stages at Woods' N well corroborates isotopic analyses showing the Matanuska R. is the primary groundwater source.

- There were approximately 37 groundwater rises not attributable to the Matanuska; 29 occurred in winter or spring, 8 in late fall, but none clearly related to the high July-August precipitation (which also coincided with high evapotranspiration).

- Three of the wells were downgradient of catch basins; they accounted for 23 of the distinct rises, generally greater magnitude than other wells (except Woods' N well).

- The high correlation between proximity to catch basins and groundwater recharge indicates the importance of runoff. These wells were (are still) in primarily agricultural settings, cleared, level to hilly, planted with hay or other crops, and where retaining moisture to minimize irrigation needs is important.

- Local recharge from precipitation is primarily in depressions and ditches that collect runoff, even from relatively flat fields with very little slope.

- The non-responsiveness to seasonal precipitation shown by the deep wells indicates most recharge occurred long ago (as indicated by isotope analyses) and as far as the Talkeetna Mts., where there is far greater precipitation and percolation.

The effects of the 1964 earthquake on well water levels:

- Woods' N well had no apparent fluctuation.

- Woods' S well water level rose 30 ft, was erratic for a month, and then dropped to the original level after four months.

- The four wells at the Experiment farm dropped from 2-20 ft, and recovered all or most within weeks or a couple months.

- The Linn well was unique; water levels fell 23 ft in December and January preceding the earthquake, recovered 15 ft before the quake, then rose and fell for the last two records. This well apparently was reused, but is now abandoned.

- There are no known reports of the 1964 earthquake on the area's groundwater, and the USGS hydrology department was unaware of this well data. I cannot detect any long-term changes attributable to the earthquake.

Examination of MSB CLF Leachate Collection Relative to Precipitation:

I investigated leachate generation at the MSB Central Landfill (CLF) and compared conditions with the proposed monofill to estimate percolation under similar conditions and alternate design goals. CLF installed the first lined cell and began collecting leachate in 2004, then added additional cells in 2008 and 2010. Leachate volume hauled to Anchorage was divided by collection area to derive the inches per year of percolation.

Annual and monthly precipitation was obtained from the three nearby NOAA weather stations, Experiment Farm, Job Corp, and Palmer Airport. Figure 10 shows the spreadsheet calculation results of percolation per year, corresponding precipitation at each station, and ratio of percolation to precipitation. The average reported precipitation varied considerably

from year to year and between stations. The Job Corp data yielded the lowest standard deviation for the percolation/precipitation ratio, and was presumed to best fit the location.

Summary results include:

- Percolation varied between 2.57 and 4.79 inches/yr. The average for nine years was 3.67 inches /yr and 4.35 inches/yr for 2010-2013. Average precipitation for these periods was 115% and 136% of the Job Corp station long term average.

- The Deep Percolation Model (see Figure 4) places the CLF location near the upper edge of the 1.5-4 inches/yr groundwater recharge zone for an average precipitation year. Adjusting each percolation average by its corresponding ratio to long term precipitation, the long term average percolation is 3.2 inches per year for each period. This apparently validates the model for this area and by extension to the adjacent proposed monofill location, which is at the upper edge of the 0-1.4 inches/yr zone.

- The CLF cells are surfaced with very porous sandy gravel daily cover and not intended to shed water. A monofill designed to shed water with intermediate caps at each lift logically could reduce cell percolation through the proposed monofill to less than the 1.4 inches/yr predicted by the model. An engineered final cap installed when closed would further reduce percolation.

Current Stage of Groundwater Level at Proposed Monofill Site:

Given the multi-year fluctuations in groundwater levels, it is important to estimate the relative groundwater level stage. This requires examining historical maxima and minima of groundwater levels and related factors in both the Palmer terrace and northwest of the site. Lines of evidence, in order of increasing historical span, include:

- Brailey Hydrologic Consultants reported groundwater monitoring above and below the excavated ponds from 2002-2010 and Dowl HKM[xxv] reported monitoring pond levels from 2007 to 2012 showing similar levels and seasonal fluctuations when data overlapped. EMI continued the monitoring of the ponds; the highest levels for the west pond were in 2013, and apparently are now decreasing.

- The City of Palmer has recorded stream flow at the WWTP monthly since 2007 and intermittently since 2001. This stream drains a portion of the Palmer terrace, related to the major groundwater source on the northeast side of the monofill. During summer, overflow or groundwater from the floodplain can swell the creek, but in winter this creek gets groundwater from the northeast. Figure 12 shows the creek flow, Matanuska R. flow, and precipitation for 2007- 4/2014. This shows 2013 had the highest levels in this period.

- The highest average groundwater levels from quarterly monitoring of the 12 active CLF wells (records extend to 1991) occurred during late 2013[xxvi].

- I've observed levels of the spring-fed pond adjacent to my house ~5 miles north of the proposed monofill since 1979. The winter of 2013-2014 had the highest level, ~1 ft above the previous highest year. Water level has dropped ~8 inches since January.

- Groundwater level maxima spanning a longer period can be inferred from the tree line abutting marshes surrounding local lakes. During seasons of low water, the marsh is colonized by trees which die when the water rises. Where water covers the ground surface during a large part of the growing season, birch or white spruce rarely survive to maturity. Baird Lake elevation varies 3.5 - 4 ft[xxvii], and the northeast bay is sometimes a separate lake when the water is low. On 4/26/14, the lake level had submerged ground supporting alder, and had reached the line of mature birch (see Photos, p 3).

These lines of evidence indicate the winter of 2013-2014 is close to a multi-decadal high groundwater level in both the Wasilla Cr. and Palmer terrace watersheds upgradient of the proposed monofill site.

Further discussion and summary of this appendix is included in the report.

Baird Lake, photos 10-13, lies upgradient of the proposed monofill. Photo 10 is a 1939 aerial showing the northeast bay of the lake at high water, and photo 11 shows it at relatively low water with only a narrow stream remaining between the bay and lake. Larry Vasanoja and his sister Marcella described playing there in the late 1930's, and recalled Baird's descriptions of the first structures built by the original homesteader; his mule shed was close to the lake, which rose and submerged the lower log courses. The log corduroy roadbed across the mouth of the bay allowed driving a wagon to the spring; it was submerged ~ 4 ft in 1936-38. Marcella showed me the site much later; there was no water connection between the bay and lake.

Photos 12-13 show the bay, with water extending to the trees, relatively close to the 1939 outline.

10-11. NE bay of Baird's Lk. Left, USDA aerial from October 1939; right Google aerial from 4/14/11

This letter acknowledges that you have submitted a complete No Exposure Certification for exclusion from the NPDES industrial storm water permitting requirements. This facility has been granted exclusion from permitting under the terms and conditions imposed by the DEC's Storm water Multi-Sector General Permit (MSGP). Exclusion for this site began on **June 3, 2013.**

As stated above, this letter acknowledges receipt of a complete No Exposure Certification. However, it is not a DEC determination of the validity of the information you provided. Your eligibility for exclusion is based on the validity of the certification you provided. Your signature on the No Exposure Certification form certifies that you have read, understood, and are implementing all of the applicable requirements. An important aspect of this certification requires that you correctly determine whether you are eligible for exclusion.

Please note that a complete No Exposure Certificate must be submitted every five years. If conditions change resulting in the exposure of materials and activities to storm water, you must obtain coverage under an NPDES storm water permit immediately.

An electronic copy of the MSGP and additional storm water guidance material can be viewed and downloaded on the Alaska DEC's storm water website at www.dec.alaska.gov/water/wnpspc/stormwater/Index.htm.

If you have any questions regarding your No Exposure Certification or other questions concerning the MSGP, please call the ADEC contact: William Ashton (907)269-6283.

Re: Clean Water Act Jurisdiction
Palmer Monofill Site (Section 18, T17N, R2E, SM; N61.55° W149.17°)

Mr. Durand,

This brief report summarizes my evaluation of the potential jurisdictional status under the Clean Water Act of the Palmer Monofill Site located in the Matanuska-Susitna Borough, Alaska.

The site includes an inactive gravel mine (pit). The gravel mine was originally excavated from uplands and was in operation for many years until ceasing at an unknown date. Portions of the inactive gravel pit have accumulated water and developed vegetation cover that indicates the development of wetlands. Most wetlands and waters generally are covered under the jurisdiction of the Clean Water Act, regulated by the Department of the Army, Corps of Engineers and the Environmental Protection Agency (EPA). Some waters and wetlands are not jurisdictional due to their lack of connection with navigable waterways that flow to the sea or tributaries of these. Jurisdictional status is also linked to interstate commerce and in cases where a water or wetland provides significant contribution to interstate commerce (e.g., fishing, bird watching, boating, etc.), jurisdiction can be demonstrated.

There are no flowing streams or rivers in proximity to the site; the nearest is Spring Creek located about 1 mile to the south and the Matanuska River located about a 1 mile to the southeast. There are lakes in the area, the nearest to the site include Bradley Lake located approximately 1,800 feet southwest and Canoe Lake located west of the site about 1,800 feet of the flooded portion of the gravel mine. There are no streams, canals, ditches, or other features that provide a continuous surface connection between the flooded gravel pit and the lakes, the Matanuska River, or Spring Creek.

The evaluation of potential Clean Water Act jurisdiction is based on the published guidance of the Department of the Army, Corps of Engineers[1]. The guidance identifies the wetlands and waters that are considered jurisdictional, which include:

- Traditional Navigable Waters (TNWs);
- Wetlands adjacent to traditional navigable waters;
- Non-navigable tributaries of TNWs that are relatively permanent waters (RPWs)[2];
- Wetlands that directly abut such tributaries.

[1] Clean Water Act Jurisdiction Following the U.S. Supreme Court's Decision in Rapanos v. United States & Carabell v. United States. December 02, 2008. Obtained online at www.usace.army.mil/Missions/CivilWorks/RegulatoryProgramandPermits/RelatedResources/CWAGuidance.aspx

[2] Typically flow year-round or have continuous flow at least seasonally (e.g., typically three months).

Other wetlands and waters must be demonstrated to have a significant nexus with TNWs to qualify for jurisdiction. A significant nexus analysis will assess the flow characteristics and functions of the tributary itself and the functions performed by any wetlands adjacent to the tributary to determine if they significantly affect the chemical, physical and biological integrity of downstream traditional navigable waters. Significant nexus also includes consideration of ecologic factors including the following: the potential of tributaries to carry pollutants and flood waters to TNWs; provision of aquatic habitat that supports a TNW; potential of wetlands to trap and filter pollutants or store flood waters; and maintenance of water quality in TNWs.

The jurisdictional guidance also clarifies the geographic features generally are not jurisdictional waters, including swales or erosional features (e.g. . gullies, small washes characterized by low volume, infrequent, or short duration flow); ditches (including roadside ditches) excavated wholly in and draining only uplands and that do not carry a relatively permanent flow of water; non-navigable tributaries that are not relatively permanent.

Although the guidance does not specifically address gravel pits excavated from uplands that have flooded, evaluation of the site indicates that waters and associated wetlands at the site are in fact not jurisdictional because these are *intrastate, isolated* waters. There is no continuous surface connection with the nearest TNWs (Bradley Lake and Canoe Lake), which without a connection are too distant from the site (1,800 feet) to provide significant aquatic habitat support to these TNWs. The waters and wetlands within the flooded gravel pits do not contribute to interstate commerce through recreation or other activities. Therefore, the aquatic features within the partially-flooded gravel pits at the site are not jurisdictional under the Clean Water Act.

Conclusions

The potential Clean Water Act jurisdictional status of the partially-flooded gravel pits located at the proposed Palmer Monofill Site has been evaluated and determined to be negative. The aquatic features including surface water and wetlands within the pits are *intrastate, isolated* waters and therefore are not jurisdictional.

This determination is preliminary and has not been corroborated with the Corps of Engineers, who make final determinations of jurisdiction under the Clean Water Act.

Please feel free to contact me if you have questions or comments.

Sincerely,
Hemlock Scientific, LLC

Subject: RE: News on Public Comment

I spoke with the MatSu Borough and looks like their process is much further out. Because you can't do much without their green light, we probably won't race to issue this permit but so far we feel the application is complete and nobody has presented any information for us to be suspicious of the proposal.

Chapter 60. Solid Waste Management.

Article

1. General Standards, Requirements, and Limitations (18 AAC 60.005 - 18 AAC 60.040)
2. Waste Disposal Permit (18 AAC 60.200 - 18 AAC 60.270)
3. Municipal Solid Waste Landfills (18 AAC 60.300 - 18 AAC 60.398)
4. Monofills (18 AAC 60.400 - 18 AAC 60.495)
5. Land Application of Biosolids (18 AAC 60.500 - 18 AAC 60.510)
6. User Fees (18 AAC 60.700 - 18 AAC 60.730)
7. Monitoring and Corrective Action Requirements (18 AAC 60.800 - 18 AAC 60.860)
8. General Provisions (18 AAC 60.900 - 18 AAC 60.990)

Editor's note: Some regulations in this chapter, which was reorganized and revised in 1996, were further changed, effective 10/29/98, and distributed in Register 148, January 1999.

The regulations in this chapter, effective 1/28/96, and distributed in Register 137, constitute a comprehensive reorganization and revision of this material. They replace all previous regulations in this chapter that were repealed simultaneously with the adoption of these regulations. The history line at the end of each section does not reflect the history of the replaced provisions before 1/28/96, nor is the section numbering related to the numbering before that date. Some section numbers in this revision were used in previous versions, but the current sections with those numbers are not necessarily related to the previous section numbers. Previous versions of this chapter, and amendments to those versions, may be reviewed at the Office of the Lieutenant Governor and may be found at Register 47, effective 7/19/73; Register 67, effective 8/21/78; Register 88, effective 10/9/83; Register 103, effective 9/20/87.

As of Register 151 (October 1999), the functions of the former Department of Community and Regional Affairs were transferred to other state agencies. Revisions to regulations to reflect changes in state agencies' names were made by the regulations attorney in accordance with ch. 58, SLA 1999 and AS 44.62.125(b)(6).

Article 1. General Standards, Requirements, and Limitations.

07. Solid waste used as fill
08. Beneficial use
10. Accumulation, storage, and treatment
15. Transport
20. Hazardous waste
25. Polluted soil
30. Medical waste
35. Vehicles and construction equipment
40. Wellhead protection

18 AAC 60.005. Purpose and applicability. (a) The purpose of this chapter is to promote cost-effective, environmentally-sound solid waste management and to ensure that landfills are designed, built, and operated to minimize health and safety threats, pollution, and nuisances. Each type of solid waste that is disposed in a landfill must be placed only in a landfill that meets the standards for that type of waste.

(b) Except as described in (c) of this section, this chapter applies to any person who accumulates, stores, transports, treats, or disposes of solid waste. The general requirements of 18 AAC 60.005 - 18 AAC 60.265 and 18 AAC 60.800 - 18 AAC 60.860 supplement the specific requirements for

(1) municipal solid waste landfills (MSWLF) as covered by 18 AAC 60.300 - 18 AAC 60.398;

(2) monofills as covered by 18 AAC 60.400 - 18 AAC 60.495; and

(3) land application of biosolids as covered by 18 AAC 60.500 - 18 AAC 60.510.

(c) The following wastes and materials, if disposed of or used as described in this subsection, are exempt from the requirements of this chapter unless mixed with nonexempt waste, there is a public health, safety, or welfare threat or environmental problem associated with management of the waste or material, or the waste or material is being managed in a manner that causes or contributes to a nuisance:

(1) landclearing waste, including excavated dirt, rock, soil, butt ends, stumps, and other similar waste;

(2) tree limbs and other foliage or woody debris, sometimes referred to as "slash," in a timber harvest area;

(3) bricks, mortar, and Portland cement type concrete, including reinforcing steel that cannot be easily removed;

(4) crumb rubber used in asphalt paving;

(5) crushed glass;

(6) domestic wastewater, nondomestic wastewater, and other wastes that are subject to a permit under AS 46.03, 18 AAC 72, or 33 U.S.C. 1342 (Federal Water Pollution Control Act, sec. 402), as amended through August 21, 1998;

(7) septage or septic tank pumpings that contain less than five percent solids by weight regulated under 18 AAC 72;

(8) waste rock from a mining operation;

(9) tailings from placer mining that have not been amalgamated or chemically treated; other mine tailings are regulated under 18 AAC 60.455;

(10) mining waste regulated by the Federal Surface Mining Control and Reclamation Act of 1977, 30 U.S.C. 1201 - 30 U.S.C. 1328, as amended through August 21, 1998, and by the Alaska Surface Coal Mining Control and Reclamation Act (AS 27.21), as amended through August 21, 1998;

(11) wood waste generated in amounts less than 10 cubic yards yearly, or in larger amounts if the conditions listed in this paragraph are met; wood waste that does not meet these conditions is regulated under 18 AAC 60.005 - 18 AAC 60.265, 18 AAC 60.480, and 18 AAC 60.800 - 18 AAC 60.990; the conditions that must be met are, as follows:

(A) the wood waste is used to construct roads, building pads, or parking areas;

(B) the use of wood will not diminish the life span or capabilities of the project when compared with other materials typically used in such projects;

(C) the project complies with the water quality standards in 18 AAC 70; and

(D) the wood waste in the project is no more than 10 feet thick at any location;

(12) source, special nuclear, or byproduct material as defined in 42 U.S.C. 2014 (Atomic Energy Act), as amended through August 21, 1998;

(13) crushed asphalt pavement used

(A) in a building pad or parking area as road base, or pavement; or

(B) as a material to construct a containment berm for a tank farm;

(14) any treated waste allowed by the department to be managed as exempt waste under 18 AAC 60.005(e);

(15) soil containing a hazardous substance that does not meet the definition of "polluted soil" in 18 AAC 60.990;

(16) other solid wastes and materials placed on the land which meet the conditions established in 18 AAC 60.007.

(d) A treatment works designed to treat less than five tons of waste daily or 10 tons in a single batch is exempt from the requirements of this chapter unless it causes or contributes to a threat to public health, safety, or welfare, or the environment or unless the works is operated in a manner that causes or contributes to a nuisance.

(e) If a person treats a waste and demonstrates to the department's satisfaction that the potential for a release of hazardous constituents is eliminated by the treatment and the treated waste will not present a threat to the public health, safety, or welfare, or to the environment, the department will allow the treated waste to be managed as an inert waste under 18 AAC 60.460 or an exempt waste under (c) of this section. The operator of the treatment works must

(1) secure the approval of the department before handling the waste as inert or exempt under this subsection; and

(2) keep records demonstrating that all waste managed under this subsection was treated in the manner on which the approval was based. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148; am 7/11/99, Register 151; am 9/7/2002, Register 163)

Authority:	AS 44.46.020	AS 46.03.100	AS 46.03.810
	AS 46.03.010	AS 46.03.110	AS 46.06.080
	AS 46.03.020	AS 46.03.800	

18 AAC 60.007. Solid wastes used as fill. (a) A person may place the following solid wastes on the land for a fill project that meets the conditions in this section:

(1) wood waste;

(2) inert waste;

(3) coal ash;

(4) crushed pavement;

(5) other similar solid wastes approved by the department.

(b) A person may not use the following wastes as fill:

(1) animal waste;

(2) asbestos;

(3) biosolids;

(4) commercial solid waste;

(5) drilling waste;

(6) hazardous waste;

(7) household waste;

(8) industrial solid waste;

(9) medical waste;

(10) mining waste;

(11) pathological waste;

(12) PCB waste;

(13) putrescible waste;

(14) selected isolation waste;

(15) sewage solids;

(16) tires;

(17) vehicles and construction equipment.

(c) A person may not place solid waste on the land until the person has submitted a proposal to the department, and that proposal has been approved. A proposal submitted under this section must include the following:

(1) an appraisal or assessment showing the current value of the property where the solid waste is to be placed;

(2) a list of each waste to be placed at the site, including the expected volume and the source of each waste type;

(3) the proposed future use of the site;

(4) an estimate of the value the property will have after the solid waste is in place;

(5) an operations plan explaining where and when the various wastes will be placed on the land;

(6) an estimate of the expected compaction density and load bearing capacity of the finished fill;

(7) a list of each permit and approval issued or expected to be issued by other government agencies;

(8) construction drawings showing

(A) surface contours of the existing site;

(B) surface contours of the finished site;

(C) the location and details for all drainage ditches and culverts to be installed;

(D) the location of any temporary or permanent road or ramp; and

(E) any pavement, sewer, plumbing, or electrical installation.

(d) The department will approve a proposal for solid waste disposal under this section within 30 working days after receipt of the request, if the waste meets the conditions listed in (b) of this section, the person requesting permission has submitted the information required under (c) of this section, and the department finds that the project will

(1) increase the market value of the property;

(2) not shift, erode, or settle in a way that will preclude proposed future use of the site;

(3) not create any harmful leachate;

(4) not undergo combustion; and

(5) not cause a threat to the public health, safety, or welfare, or to the environment. (Eff. 9/7/2002, Register 163)

Authority: AS 44.46.020 AS 46.03.100 AS 46.03.810
AS 46.03.010 AS 46.03.110 AS 46.06.080
AS 46.03.020

18 AAC 60.008. Beneficial use. (a) If a person wants to use a solid waste other than the solid wastes specified in 18 AAC 60.007(a), for beneficial purposes other than the land placement options specified in 18 AAC 60.007(a), that person shall submit a proposal explaining the proposed use and all features of the proposal that are incorporated to protect public health, safety, and welfare, and the environment.

(b) The department will review the proposal and exempt the solid waste from some or all of the requirements of this chapter if the department finds that the proposal adequately protects public health, safety, and welfare, and the environment. (Eff. 9/7/2002, Register 163)

Authority: AS 44.46.020 AS 46.03.100 AS 46.03.810
AS 46.03.010 AS 46.03.110 AS 46.06.080
AS 46.03.020

18 AAC 60.010. Accumulation, storage, and treatment. (a) A person may not store accumulated solid waste in a manner that causes

(1) a litter violation under 18 AAC 64.015;

(2) the attraction or access of domestic animals, wildlife, or disease vectors;

(3) a health hazard; or

(4) polluted run-off water.

(b) A person who sponsors an event that is open to the public and at which solid waste is generated shall

(1) collect, store, transport, and dispose of the solid waste at a solid waste disposal facility that has a permit or is otherwise authorized under this chapter; or

(2) make contractual or other arrangements for the proper collection, storage, transportation, and disposal of that waste at a solid waste disposal facility that has a permit or is otherwise authorized under this chapter.

(c) A person who has made contractual or other arrangements for the collection, storage, transportation, and treatment of solid waste is not relieved of the responsibility for that waste if the contractor fails to manage the waste in compliance with this section.

(d) A person shall dispose of a carcass

(1) of livestock, including poultry, infected with a communicable disease, only if authorized by the state veterinarian and in accordance with 9 C.F.R. 53.4, revised as of January 1, 1998, adopted by reference;

(2) of any animal not described in (1) of this section, other than open range livestock, unless the carcass is used as food for humans or animals,

(A) at a landfill that operates in accordance with a permit issued under this chapter;

(B) by cremation or incineration in an incinerator that complies with 18 AAC 50; or

(C) by burial on land, with the landowner's permission; and

(3) of any animal not disposed under (1) or (2) of this subsection that the department determines is causing a nuisance or threat to the public health, safety, or welfare or to the environment, by one of the methods set out in (2) of this subsection.

(e) Subject to 18 AAC 60.040(b), a person who wishes to dispose of organic waste from a commercial slaughterhouse or fish processing waste may apply that waste to agricultural or silvicultural land for soil enhancement purposes if the waste is

(1) ground up to less than two inches in diameter;

(2) treated by a method described in 40 C.F.R. 503.15, revised as of July 1, 1997, adopted by reference, to reduce the number of *salmonella* spp. or fecal coliform bacteria present to meet the Class A requirements for pathogen reduction at the time of land application;

(3) incorporated into the soil surface when the waste is applied;

(4) applied at or below the agronomic rate for nitrogen for any crop or vegetation that will be grown on that land;

(5) applied in a manner that does not create an odor nuisance or attract animals or other vectors; and

(6) applied in a manner that ensures that run-off of surface water from the disposal site does not violate the water quality standards in 18 AAC 70.

(f) The owner or operator of a transfer station designed to hold 20 cubic yards or more of waste shall

(1) use containers with covers, fencing, or another department-approved method to prevent wind and animals from scattering the waste;

(2) pick up litter as necessary to prevent a violation of AS 46.06.080;

(3) manage the site so that the standards in 18 AAC 60.230 for disease vectors and animal control are met; and

(4) prevent or control run-off that would violate 18 AAC 70.

(g) If the department finds that a transfer station that is not part of a facility holding a permit under this chapter is causing a nuisance or a risk to public health or safety or to the environment, the department will require the operator to submit a facility design and operating plan explaining how the operator will

(1) meet the requirements of (f) of this section;

(2) conduct operations to prevent a fire at the transfer station;

(3) promptly extinguish any fire that occurs;

(4) control odor and dust as necessary to prevent a public nuisance;

(5) provide safe public access to the facility as necessary;

(6) manage hazardous waste abandoned by others at the facility; and

(7) prevent or control run-off that would violate 18 AAC 70.

(h) Except as provided for drilling waste in 18 AAC 60.430, if the department finds that a facility used to store more than 50 tons of materials for reuse, recycling, or resource recovery, or more than 50 tons of solid waste before disposal, is causing or contributing to a nuisance or poses a risk to public health, safety, or welfare, or to the environment, the department will require the operator to meet one or more of the following requirements:

(1) provide proof to the department that the landowner has consented to the waste storage activity, unless the operator owns the property;

(2) remove the materials from the facility or store materials at the facility for no more than one year;

(3) use containers with covers, fencing, or another department-approved method to prevent litter;

(4) pick up litter as necessary to prevent a violation of AS 46.06.080;

(5) manage the facility so that the standards in 18 AAC 60.230 for disease vectors and animal control are met;

(6) prevent fire at the facility;

(7) promptly extinguish any fire that occurs;

(8) prevent or control run-off that would violate 18 AAC 70;

(9) control odors, noise, and dust as necessary to prevent a nuisance;

(10) provide safe public access to the facility as necessary;

(11) manage hazardous waste abandoned by others at the facility;

(12) monitor the temperature of waste piles to detect combustion; and

(13) take other appropriate action.

(14) repealed 9/7/2002.

(i) The owner or operator of a solid waste treatment works that is designed to treat more than five tons of waste daily, and that is not located within the boundaries of a permitted landfill shall

(1) use containers with covers, fencing, or any other short-term, department-approved storage method to prevent wind and animals from scattering the waste;

(2) pick up litter as necessary to prevent a violation of AS 46.06.080;

(3) manage the treatment works so that the standards in 18 AAC 60.230 for disease vectors and animal control are met;

(4) control odors as necessary to prevent a public nuisance;

(5) prevent or control run-off that would violate 18 AAC 70;

(6) prevent fire at the treatment works;

(7) promptly extinguish any fire that occurs;

(8) provide safe public access to the site as necessary;

(9) control dust;

(10) manage hazardous waste abandoned by others at the treatment works; and

(11) take other appropriate action.

255. General permit
260. Permit termination and modification
265. Proof of financial responsibility
270. Termination of post-closure obligations

18 AAC 60.200. Permit requirement. (a) Except as otherwise provided in this section, a person may treat or dispose of solid waste, or construct, modify, or operate a solid waste facility only in accordance with a waste disposal permit issued by the department under 18 AAC 60.215, an authorization under (c) or (d) of this section, or a research, development, and demonstration permit issued under 18 AAC 60.213. However, a permit or authorization under this chapter is not required for

(1) a single-family or duplex residence or a farm where solid waste is generated and disposed of on the premises;

(2) the closure of an inactive reserve pit, solid waste facility, or dump;

(3) disposal that is governed by a permit issued under 18 AAC 72.010, 18 AAC 72.210, or an approved contaminated site cleanup plan under 18 AAC 75 or 18 AAC 78;

(4) disposal that is governed by a permit issued under 18 AAC 62 or under 40 C.F.R. Part 264 or 40 C.F.R. Part 265, revised as of July 1, 1998, adopted by reference;

(5) disposal under an underground injection permit issued under 42 U.S.C. 300h-4 (Safe Drinking Water Act);

(6) a person who transports solid waste to an approved facility;

(7) a facility that is used only for the disposal of material and waste exempted by 18 AAC 60.005(c);

(8) a transfer station, except one that is located at a facility otherwise subject to this section;

(9) a reuse, recycling, or resource recovery facility unless the department determines that the facility is causing or is likely to cause excessive odor or other problems such as combustion, blowing litter, water quality degradation, or vermin attraction;

(10) a solid waste treatment works or a solid waste treatment facility that is designed to treat less than five tons of waste daily;

(11) drilling, trenching, and other activities described in AS 46.03.100(f) that are not subject to the permit requirements of AS 46.03.100;

(12) animal or fish waste disposed under 18 AAC 60.010(d) or (e);

(13) polluted soil that is polluted only because of a naturally occurring metal if the soil is returned to the location where the soil was excavated or taken to another area with an equal or greater concentration of the same metal; or

(14) storage of industrial solid waste under 18 AAC 60.430(a);

(15) waste approved for use as fill under 18 AAC 60.007;

(16) waste approved for beneficial use under 18 AAC 60.008; or

(17) waste managed under a plan approved under 18 AAC 60.207.

(b) If the department certifies an activity under 33 U.S.C. 1344 (Clean Water Act, section 404) and attaches conditions to that certification, and if the department decides that certification may be substituted for a permit required under this chapter, the department will enforce the terms and conditions of the certification in the same way it would require compliance with a permit issued under this chapter for the same activity.

(c) The department will authorize the disposal of municipal solid waste in a Class III MSWLF meeting the requirements of 18 AAC 60.300(c)(3)(B), if

(1) the landfill serves an average daily population of fewer than 50 persons;

(2) the landfill is sited and operated in accordance with the requirements of this chapter;

(3) the owner or operator of the landfill

(A) submits for department review a completed authorization request form provided by the department and any other information that the department considers necessary to ensure that the landfill is sited and operated in accordance with the requirements of this chapter; and

(B) receives written notice from the department that the authorization request has been approved; and

(4) not later than 30 days before the end of each five-year period after the date of a previous authorization under this subsection, the owner or operator of the landfill confirms continued eligibility under (1) and (2) of this subsection by submitting the information that the department requests for that purpose.

(d) The department will authorize the disposal of solid waste in a one-time-use landfill, if

(1) the proposed location meets the requirements of 18 AAC 60.410;

(2) the proposed one-time-use landfill is associated with a project located in an area

(A) that does not have year-round ground access to a system of connected roads with a total length of 100 miles or more; or

(B) where all permitted landfills are more than 100 road miles away or have refused, in writing, to accept the waste;

(3) the owner or operator of the one-time-use landfill

(A) submits for department review a completed authorization request form provided by the department; on the form, the owner or operator must agree to open, operate, and close the landfill in accordance with

(i) the applicable provisions in 18 AAC 60.400 – 18 AAC 60.490 for the specific waste type; and

(ii) any other conditions that the department requires to ensure the protection of the public health, safety, and welfare and the environment;

(B) provides documentation to the department that the landowner consents to the proposed activity; and

(C) receives written notice from the department that the authorization request has been approved;

(4) of the following solid waste types, the proposed landfill will receive only one single type at not more than the listed volume:

(A) 1,000 cubic yards of inert waste;

(B) 250 cubic yards of regulated asbestos-containing materials;

(C) 1,000 cubic yards of domestic sewage solids;

(D) an approved volume of any other solid waste that the department considers to pose a low risk to the environment; and

(5) the one-time-use landfill will be closed not later than one year from the date of initial waste disposal indicated in the authorization request, unless the owner or operator

(A) requests a longer term;

(B) demonstrates that a longer term is necessary to the project; and

(C) receives written approval of the longer term from the department.

(Eff. 1/28/96, Register 137; am 10/29/98, Register 148; am 7/11/99, Register 151; am 9/7/2002, Register 163; am 9/5/2010, Register 195; am 4/12/2013, Register 206)

Authority: AS 44.46.020 AS 46.03.100 AS 46.06.010
AS 46.03.010 AS 46.03.800 AS 46.06.080
AS 46.03.020 AS 46.03.810

18 AAC 60. 203. Design approval. For facilities that require a permit or authorization under 18 AAC 60.200 or 18 AAC 60.211, the owner of the facility must have prior written approval from the department of the facility design in order to construct a new facility or a lateral expansion of an existing facility. Drawings, documents, and plans showing that the facility design will meet the applicable requirements of this chapter may be submitted for department approval either separately or as part of a permit application. (Eff. 4/13/2013, Register 206)

Authority: AS 46.03.010 AS 46.03.100 AS 46.06.080
AS 46.03.020 AS 46.03.710

(2) unless the applicant submits a request for renewal in writing, using a form provided by the department; the request must include

(A) a detailed assessment of the project, showing the status with respect to achieving project goals, and a list of problems and progress towards resolution of those problems; and

(B) other information that the department requests and that the department considers relevant to compliance by the applicant with this chapter. (Eff. 9/5/2010, Register 195)

Authority:	AS 44.46.020	AS 46.03.100	AS 46.03.810
	AS 46.03.010	AS 46.03.110	AS 46.06.010
	AS 46.03.020	AS 46.03.800	AS 46.06.080

18 AAC 60.215. Permit issuance. (a) Except for a research, development, and demonstration permit issued under 18 AAC 60.213, the department will issue or deny a permit after reviewing information contained in the application and the public record, based upon the

(1) applicable provisions of this chapter and 18 AAC 15;

(2) air quality control regulations in 18 AAC 50;

(3) water quality standards in 18 AAC 70;

(4) wastewater disposal regulations in 18 AAC 72;

(5) drinking water standards in 18 AAC 80;

(6) repealed 4/8/2012;

(7) Alaska Historic Preservation Act, AS 41.35.010 - 41.35.240;

(8) long-term stability of the facility and related structures in areas subject to natural events such as aufeis, floods, earthquakes, avalanches, landslides, mudflows, land slippage, or thaw-unstable permafrost; and

(9) applicant's compliance history while conducting other operations regulated by the department under this title, including any notice of violation, mandatory compliance order, consent order, and any other administrative, civil, or criminal enforcement action; an applicant's compliance history will constitute sufficient basis for denial of approval if, in the department's determination, that history shows a pattern or practice of noncompliance that demonstrates the applicant's unwillingness or inability to achieve or maintain compliance with provisions of this chapter.

(b) The department will attach conditions to the permit

(1) to ensure compliance with applicable state law;

(2) that incorporate the standards of this chapter relating to siting, design, construction, operation, and closure of the facility; and

(3) to ensure that dust, odor, and safety hazards are kept to a minimum.

(c) The permittee shall provide timely, adequate notice to the department of any change in the permittee's mailing address or physical residence. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148; am 9/5/2010, Register 195; am 4/8/2012, Register 202)

Authority: AS 44.46.020 AS 46.03.100 AS 46.03.810

AS 46.03.020 AS 46.03.800

18 AAC 60.220. Access requirements. Except for a facility that treats or disposes of biosolids and is subject to 18 AAC 60.500 - 18 AAC 60.510, the owner or operator of a facility subject to the permit requirements of AS 46.03.100 or this chapter shall

(1) control public access;

(2) prevent unauthorized vehicular traffic and illegal dumping of wastes by using artificial barriers, natural barriers, or both; the requirements of this paragraph do not apply to a Class III MSWLF unless it is connected to a major road system;

(3) ensure that public salvaging, if allowed, is performed in an area that does not hinder facility operations, create a safety hazard, or cause pollution; and

(4) ensure that access and onsite roads under the operator's control are kept passable and safe for vehicles during normal hours of operation. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148)

Authority: AS 44.46.020 AS 46.03.100 AS 46.03.810

AS 46.03.010 AS 46.03.110 AS 46.06.080
AS 46.03.020

18 AAC 60.225. Surface water requirements. (a) The owner or operator of a solid waste disposal facility may not allow the placement of solid waste in surface water unless that placement is allowed in a permit issued under AS 46.03.100 and this chapter.

(b) Except for an inert waste landfill, an asbestos landfill, or a Class III MSWLF that meets the standards in 18 AAC 60.300(c)(3)(B), the owner or operator of a landfill shall

(1) remove all ponded water that is in contact with waste within seven days after the formation of the pond unless another dewatering schedule is specified in a permit issued under AS 46.03.100 and this chapter;

(2) if the department determines that a control system for stormwater run-off is necessary to prevent the landfill from contributing to siltation or flooding problems in nearby surface water bodies construct and maintain a control system capable of containing and controlling the run-off from a 24-hour, 25-year storm; and

(3) prevent, contain, or control visible leachate seeps at the boundary of the waste management area.

(c) Except for a Class III MSWLF that meets the conditions of 18 AAC 60.300(c)(3)(B), or a Class I MSWLF with a research, development, and demonstration permit under 18 AAC 60.213 that allows the Class I MSWLF to utilize methods that vary from the requirements of this subsection, the owner or operator of a solid waste disposal facility shall construct and maintain a control system that will prevent run-on from flowing onto the active portion of the facility. The control system must be capable of handling the peak discharge from a 25-year storm.

(d) The owner or operator of an inert waste landfill, an asbestos landfill, or a Class III MSWLF that meets the standards of 18 AAC 60.300(c)(3)(B) shall

(1) minimize contact between stormwater and the waste;

(2) construct and operate the landfill so that seasonal flooding is temporary in duration and ponded water is removed within 30 days; and

(3) prevent, contain, or control visible leachate seeps at the boundary of the waste management area if the department determines that leachate control measures are necessary to prevent a potential threat to public health, safety, or welfare. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148; am 9/5/2010, Register 195)

AS 46.03.020 AS 46.03.800 AS 46.06.080

18 AAC 60.230. Disease vector, wildlife, and domestic animal control. (a) The owner or operator of a facility subject to the permit requirements of AS 46.03.100 and this chapter shall manage the facility so that

(1) disease vectors do not endanger public health, safety, or welfare or create a nuisance;

(2) wildlife and domestic animals do not endanger public health, safety, or welfare, become harmed by contact with the waste; or become a nuisance; the requirements of this paragraph do not apply to a Class III MSWLF.

(b) The owner or operator of a Class III MSWLF shall minimize, to the extent practical, access by wildlife and domestic animals to putrescible waste deposited at the MSWLF. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148)

Authority: AS 44.46.020 AS 46.03.100 AS 46.03.810

AS 46.03.020

18 AAC 60.233. Controlling impacts outside facility boundaries. The owner or operator of a landfill or solid waste treatment works shall ensure that

(1) a minimum setback of 50 feet is kept between the waste management area and the property line of the facility; and

(2) dust, odor, noise, traffic, and other effects from the operation of the facility do not become a nuisance or a hazard to the public health, safety, or welfare. (Eff. 10/29/98, Register 148)

Authority: AS 44.46.020 AS 46.03.100 AS 46.03.810
AS 46.03.010 AS 46.03.110 AS 46.06.080
AS 46.03.020 AS 46.03.800

18 AAC 60.235. Recordkeeping requirements. (a) The owner or operator of a facility subject to the permit requirements of this chapter shall maintain an "operating record." The record must be retained at a location that is readily accessible for department review and by employees working at the facility. The record must consist of

(1) the permit application and the permit;

(2) inspection records, training procedures, and notification procedures, if required by 18 AAC 60.240;

(3) any demonstration, certification, finding, monitoring, testing, or analytical data required by 18 AAC 60.800 - 18 AAC 60.860;

(4) any permit or record required under the Clean Water Act as that Act applies to leachate and stormwater discharges;

(5) financial assurance documentation if required under 18 AAC 60.265;

(6) the operations plan required in 18 AAC 60.210(b)(3)(C) or 18 AAC 60.211(b)(6);

(7) as-built drawings of the landfill; and

(8) any other documents required by this chapter to be kept in the operating record.

(b) Upon request, the owner or operator shall furnish the operating record to the department, or shall make it available at reasonable times for department inspection. (Eff. 1/28/96, Register 137; am 9/7/2002, Register 163; am 4/12/2013, Register 206)

Authority: AS 44.46.020 AS 46.03.100 AS 46.03.810
AS 46.03.010 AS 46.03.110 AS 46.06.080
AS 46.03.020

18 AAC 60.240. Procedures to exclude receipt of hazardous waste. (a) The owner or operator of a landfill shall

(1) post a clearly legible sign at the entrance to the landfill notifying users that disposal of regulated hazardous waste and polychlorinated biphenyls (PCB) waste is prohibited; and

(2) provide written notification to the department and EPA if a regulated hazardous waste or PCB waste is found at the facility.

(b) Except for a Class III MSWLF, the owner or operator of a landfill shall implement a program at the facility to detect and prevent the disposal of regulated hazardous waste and PCB waste as defined in 40 C.F.R. 761.3, revised as of July 1, 1998, adopted by reference. The program must include the following items at a minimum:

(1) random inspections of incoming loads or other methods to minimize the risk that incoming loads will contain a regulated hazardous waste or PCB waste;

(2) maintenance of records of any inspections performed under (1) of this paragraph; and

(3) training of appropriate facility personnel to recognize regulated hazardous waste and PCB waste; for purposes of this paragraph, training may include that described in the EPA's technical manual entitled *Solid Waste Disposal Facility Criteria*, Subpart C Operating Criteria, EPA530-R-93-017, November 1993, as amended through April 13, 1998.

(c) The requirements of this section do not apply to a facility that treats or disposes of biosolids and is subject to 18 AAC 60.500 - 18 AAC 60.510. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148; am 7/11/99, Register 151)

Authority:	AS 44.46.020	AS 46.03.100	AS 46.03.810
	AS 46.03.010	AS 46.03.110	AS 46.06.080
	AS 46.03.020	AS 46.03.800	

Editor's note: - The United States Environmental Protection Agency manual referred to in 18 AAC 60.240 may be reviewed at the department's offices in Anchorage, Fairbanks, and Juneau. Copies may be obtained from National Technical Information Services, 5285 Port Royal Road, Springfield, Virginia 22161.

18 AAC 60.243. Intermediate cover. (a) Except for a facility that treats or disposes of biosolids and is subject to 18 AAC 60.500 - 18 AAC 60.510 and a facility for disposal of waste that has a permit under AS 46.03.100 and this chapter to contain fluids, the owner or operator of a landfill shall apply an intermediate cover to any inactive portion of a landfill within seven days after the waste is last deposited in that area, using a soil material at least 12 inches thick, graded to prevent water from ponding.

(b) For purposes of this section, "inactive portion" means an area of a landfill that does not receive waste for a period of 90 days or more. (Eff. 10/29/98, Register 148)

Authority:	AS 44.46.020	AS 46.03.100	AS 46.03.810
	AS 46.03.010	AS 46.03.110	AS 46.06.080
	AS 46.03.020	AS 46.03.800	

18 AAC 60.245. Prompt closure. (a) Except where a different time is specified in 18 AAC 60.395(f) or is otherwise approved by the department, the owner or operator of a landfill shall place the final cover on those waste management areas that have reached final elevation within 90 days after the last waste placement.

(b) The requirements of this section do not apply to an inactive drilling waste disposal site. (Eff. 1/28/96, Register 137)

Authority:	AS 44.46.020	AS 46.03.100	AS 46.03.810
	AS 46.03.010	AS 46.03.110	AS 46.06.080
	AS 46.03.020		

18 AAC 60.250. Existing permits and permit renewal. (a) In addition to the

requirements of this section, permit renewal under this chapter is also subject to the permit renewal requirements of 18 AAC 15 and the fee requirements of 18 AAC 60.700.

(b) If an applicant for permit renewal must undertake a construction project or needs additional time to install monitoring or other equipment, the department will negotiate a compliance schedule as part of the renewal.

(c) An application for permit renewal must be submitted at least 30 days before the permit expires. (Eff. 1/28/96, Register 137; am 6/28/96, Register 138; am 9/7/2002, Register 163)

Authority:	AS 44.46.020	AS 46.03.020	AS 46.03.810
	AS 44.46.025	AS 46.03.100	AS 46.06.080
	AS 46.03.010	AS 46.03.110	

18 AAC 60.255. General permit. (a) The department will issue a general permit covering a group of facilities subject to the permit requirements of this chapter, or to a group of activities, if the facilities or activities in the group

(1) involve the same type of waste handling systems;

(2) dispose of the same type of solid waste;

(3) will not threaten public health, safety, or welfare, or the environment; and

(4) are, in the department's determination, best regulated under a general permit.

(b) The department will restrict a general permit to a limited region of the state if the department determines that the safe management and disposal of the waste depends on conditions found in that region and a general permit will protect the public health, safety, and welfare, and the environment.

(c) An applicant for a general permit shall submit to the department a petition in which the applicant demonstrates that the facilities or activities to be covered meet the conditions described in (a) of this section. A general permit may be sought by a single owner or operator, but the department will give priority to applications jointly submitted by two or more owners or operators of facilities that would be subject to the general permit. If the department approves an application for a general permit under this section or, on its own motion, proposes to create a general permit, the department will publish notice of the proposed permit in two issues of a newspaper of general circulation in the area where the waste management is to take place and in other media that the department considers appropriate. The notice will summarize the proposed permit, state where the waste management is to be allowed, state where copies of the proposed permit and supporting documents may be obtained, and state that any person who wants to express an opinion to the department may send written comments to the department within 30 days. The department will send a copy of the public notice and the proposed general permit and

supporting documents to the commissioners of

(1) fish and game;

(2) natural resources;

(3) deleted;

(4) commerce, community, and economic development; and

(5) health and social services.

(d) After the time for public comment expires, the department will grant or deny the application for a general permit or, if the general permit is one proposed by the department, will issue the permit, or decide to take no action on the proposal. A copy of the department's decision will be sent to the applicant and to any person who submitted written comments on the proposed general permit. The decision will include a statement that any person who is aggrieved by the decision may request an adjudicatory hearing under 18 AAC 15.

(e) A general permit will contain criteria by which facilities may qualify for coverage under the general permit. A person who seeks to be covered under a general permit issued under this section may submit an application to the department on a form provided by the department or in accordance with the conditions of the general permit. The application must be accompanied by the annual fee identified in Table I-4 in 18 AAC 60.700(a). In addition, the application must

(1) be submitted within the time period identified in the form for the general permit under which coverage is sought; and

(2) clearly show how the proposed activity meets the criteria and conditions of the general permit.

(f) The department will notify the applicant of its decision to grant or deny an application for coverage under a general permit within 30 days after receiving a complete application under (e) of this section.

(g) Upon 30 days written notice to the permittee, the department will modify, revoke and reissue, or terminate the coverage of a general permit to a specific facility without opportunity for a pre-revocation hearing, and will require that facility to obtain an individual permit if operations under the general permit might threaten public health or the environment. Situations indicative of such a threat include the following:

(1) the facility does not comply with a material provision of the general permit;

(2) there is a material change in the operation or in the type or quantity of waste for which the general permit was issued; or

(3) the permit was procured by misrepresentation of material fact or by failure of the applicant to fully disclose the material facts relating to its issuance.

(h) Notwithstanding 18 AAC 15.195 – 18 AAC 15.340, a person who disagrees with a department action taken under (g) of this section may request review by the director of the department's division responsible for issuing permits under this chapter. A request under this subsection must be submitted within 30 days after the action is taken and must be accompanied by a written discussion that sets out the reasons why the department's action is thought to be erroneous. The director shall issue a written decision on the matter within 30 days after receiving the request. A decision under this subsection is a final agency decision subject to judicial review under the applicable Rules of Appellate Procedure.

(i) Repealed 9/5/2010.

(j) Beginning with the calendar year following the department's approval of an application for coverage under a general permit, the owner or operator shall pay the applicable annual fee within 60 days after the date of billing. (Eff. 1/28/96, Register 137; am 6/28/96, Register 138; am 10/29/98, Register 148; am 6/30/2002, Register 162; am 7/11/2002, Register 163; am 9/5/2010, Register 195; am 4/8/2012, Register 202)

Authority:	AS 44.46.020	AS 46.03.100	AS 46.03.810
	AS 44.46.025	AS 46.03.110	AS 46.06.010
	AS 46.03.010	AS 46.03.800	AS 46.06.080
	AS 46.03.020		

Editor's note: As of Register 171 (October 2004), the regulations attorney made technical revisions under AS 44.62.125(b)(6) to reflect the name change of the Department of Community and Economic Development to the Department of Commerce, Community, and Economic Development made by ch. 47, SLA 2004 and the corresponding title change of the commissioner of community and economic development.

As of Register 171 (October 2004), 18 AAC 60.255(c)(3) was deleted by the regulations attorney because that paragraph was redundant with 18 AAC 60.255(c)(4).

18 AAC 60.260. Permit termination and modification. (a) Repealed 9/5/2010.

(b) No later than 30 days before terminating or modifying under AS 46.03.120 a permit issued under this chapter, other than a general permit subject to termination or modification under AS 46.03.120 and 18 AAC 60.255, the department will issue a written notice of termination or modification. In the notice, the department will

(1) include a clear, detailed statement describing reasons for the department's decision, including acts or omissions of the permittee that led to the department's decision to modify or revoke;

(2) clearly specify the statute, regulation, or permit condition the permittee is alleged to have violated, including the nature of the violation; and

(3) state that the permittee may request an immediate hearing before the commissioner or the commissioner's designee, if the request is submitted to the commissioner within 10 days after receipt of the notice; a request for hearing must include a written statement of reasons why the permittee believes the department's decision to be in error; failure to file a timely request for hearing constitutes a waiver of the permittee's right to a hearing.

(c) A hearing under this section will be held no later than 10 days after a request for hearing is received under (b) of this section, and the commissioner or the commissioner's designee will issue a written decision no later than 10 days after the hearing. A decision under this subsection is a final agency decision subject to judicial review. A hearing under this section will be recorded and will adhere to the evidence rules described in AS 44.62.460.

(d) If the permittee and the department agree to delay the hearing for more than 30 days after the notice is issued under (b) of this section, the department's decision remains in effect unless the permittee requests and is granted a stay by the commissioner or commissioner's designee. A request for a stay must meet the requirements of 18 AAC 15.210. (Eff. 1/28/96, Register 137; am 9/5/2010, Register 195)

Authority:	AS 44.46.020	AS 46.03.100	AS 46.03.850
	AS 46.03.010	AS 46.03.120	
	AS 46.03.020	AS 46.03.820	

18 AAC 60.265. Proof of financial responsibility. Unless the applicant has provided equivalent surety through a government agency or has demonstrated financial assurance under 18 AAC 60.398, the department will require proof of financial responsibility to cover the cost of closing a landfill and, if monitoring is required, the cost of post-closure monitoring if the department determines proof of financial responsibility is necessary to protect the public health, safety, or welfare, or the environment. Proof of financial responsibility under this section may be demonstrated by self-insurance, insurance, surety, or other guarantee approved by the department to assure compliance with applicable closure standards and post-closure monitoring requirements. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148)

Authority:	AS 44.46.020	AS 46.03.100	AS 46.03.830
	AS 46.03.010	AS 46.03.110	AS 46.06.080
	AS 46.03.020	AS 46.03.810	

18 AAC 60.270. Termination of post-closure obligations. (a) Whether or not a permit required by this chapter has been issued, once waste disposal commences at a facility subject to this chapter, the owner and operator are subject to all applicable provisions of this chapter until the owner or operator of the facility requests, and is granted approval by the department to terminate post-closure care required by 18 AAC 60.396, 18 AAC 60.397, or 18 AAC 60.490.

(b) Within 30 days after receipt of a complete request, the department will review a request for approval to terminate post-closure care under the requirements of this chapter. The request must include

(1) a report on the findings of the post-closure monitoring;

(2) drawings, photographs, and other documentation concerning the condition of the landfill at the time of the request; and

(3) an analysis of any potential problems at the landfill, including settlement, erosion, cracking, and slope instability, and what evidence will indicate a problem has developed.

(c) The department will approve a request to terminate the post-closure care requirements if the department finds that the facility does not pose a threat to public health, safety, or welfare, or to the environment.

(d) If the department, after it approves a request under (c) of this section, determines that the circumstances under which the approval was granted have changed to the extent that the facility that was granted approval under (c) of this section poses a threat to public health, safety, or welfare, or to the environment, the owner or operator of the facility must comply with the provisions of 18 AAC 60.800 - 18 AAC 60.860. (Eff. 9/7/2002, Register 163)

490. Closure demonstration and post-closure care
495. (Repealed)

18 AAC 60.400. Applicability. (a) In addition to the requirements of 18 AAC 60.005 - 18 AAC 60.265 and 18 AAC 60.800 - 18 AAC 860, the requirements of 18 AAC 60.400 - 18 AAC 60.495 apply to a person who disposes of waste that is subject to the permit requirement of AS 46.03.100, but that is not

(1) municipal solid waste subject to 18 AAC 60.300 - 18 AAC 60.397;

(2) regulated hazardous waste or waste identified as hazardous waste under 18 AAC 62.020;

(3) being disposed of under a wastewater disposal permit issued under 18 AAC 72; or

(4) subject to a plan approved under 18 AAC 75 or 18 AAC 78 for oil or other hazardous substances.

(b) A solid waste that is not specifically addressed in 18 AAC 400 - 18 AAC 60.495 will be classified by the department and assigned the most applicable waste category during the preapplication meeting conducted under this chapter.

(c) If an applicant is not sure which type of landfill standards apply, the applicant shall contact the department for a determination before applying for a permit.

(d) Repealed 10/29/98. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148; am 7/11/99, Register 151; am 8/8/2003, Register 167; am 9/5/2010, Register 195)

Authority: AS 44.46.020 AS 46.03.020 AS 46.03.110
AS 46.03.010 AS 46.03.100

18 AAC 60.410. Location standards. (a) A monofill built after 1/28/96 may not be constructed on slopes greater than 10 percent grade or unstable soils that might cause the waste to slide or settle excessively.

(b) Except for a mining waste tailings impoundment operating under a permit issued by the department, the owner or operator of a monofill located in a floodplain shall remove the waste or ensure that the monofill

(1) does not restrict the flow of a flood or significantly reduce the temporary water storage capacity of the floodplain; and

(2) is designed to protect against washout of solid waste from the facility.

(c) A new monofill, or a lateral expansion of a monofill, that is subject to 18 AAC 60.400 - 18 AAC 60.495 must be designed to protect its integrity from damage caused by natural events that could be reasonably anticipated to occur at the facility such as aufeis, floods, earthquakes, thawing of unstable permafrost, and the effects of freezing and thawing. (Eff. 1/28/96, Register 137)

Authority: AS 44.46.020 AS 46.03.020 AS 46.03.110
AS 46.03.010 AS 46.03.100

18 AAC 60.420. Operations. (a) A monofill must be operated so that

(1) dust, odor, noise, traffic, and other effects from facility operations do not become a nuisance or hazard to the health, safety, or property of persons outside the boundary of the facility; and

(2) litter is controlled by fencing or another approved means, and is removed from access roadways and other areas in the facility.

(b) Except for drilling wastes, bulk liquid wastes and containerized liquid wastes may not be placed in a monofill unless authorized by a permit issued by the department. (Eff. 1/28/96, Register 137)

Authority: AS 44.46.020 AS 46.03.020 AS 46.03.110
AS 46.03.010 AS 46.03.100

18 AAC 60.430. Drilling waste. (a) Except for an inactive reserve pit subject to 18 AAC 60.440, or drilling waste that is managed as an industrial solid waste under 18 AAC 60.485, the owner or operator of a drilling waste storage facility shall meet the storage requirements of this subsection as follows:

(5) the owner or operator demonstrates that water pollution in the affected water body is diminishing.

(k) If an inactive reserve pit is located on private property and the owner or operator seeking permanent closure approval is not the landowner of record, the owner or operator shall provide proof that the landowner has been notified of the request for permanent closure approval.

(*l*) If additional information about conditions at a closed inactive reserve pit make corrective action necessary to protect public health and the environment, or, if appropriate, supportive documentation becomes available that might help locate an inactive reserve pit closed under (h)(1) of this section, the department will require further investigation, assessment, monitoring, or remediation.

(m) The department will apply a fee described in 18 AAC 60.700(f) for any action taken by the department after initial approval or disapproval of the closure plan, including oversight of corrective action, ongoing monitoring, final inspection of closed sites, and issuance of permanent closure approval. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148; am 6/30/2002, Register 162)

Authority: AS 44.46.020 AS 46.03.090 AS 46.03.800
AS 46.03.025 AS 46.03.100 AS 46.03.810
AS 46.03.020

Editor's note: Information about how to obtain or review SW-846 is in the editor's note for 18 AAC 60.365.

18 AAC 60.450. Asbestos. (a) Waste that includes regulated asbestos-containing material (RACM) waste must be managed in a manner that prevents the release of asbestos fibers to the air or to surface water and must be disposed of in an approved RACM landfill. Non-RACM waste may be disposed of in a municipal solid waste landfill if

(1) the landfill has a permit issued under this chapter;

(2) the waste is covered within 24 hours, using procedures that prevent the release of asbestos fibers to the air or to surface water; and

(3) no fires have occurred in the landfill for more than one year.

(b) A waste management area used for disposal of RACM waste must be located on undisturbed earth or stable fill. An asbestos waste management area may not be located in a manner that would preclude future closeout or remedial action at the facility. The limits of the asbestos disposal area must be marked on property survey records, and recorded on the property deed.

(c) The operator of a facility that is receiving RACM waste shall inspect each load of RACM waste to assure that the friable asbestos material is sealed in leak-proof bags or containers, labeled in accordance with 29 C.F.R. 1910.1001(j)(4), revised as of July 1, 1998, adopted by reference; and accompanied by a complete and accurate shipment record prepared in accordance with (e) of this section or a copy, signed by the owner or operator of the facility, of the asbestos waste shipment record prepared by the transporter in accordance with 40 C.F.R. 61.149.

(d) At the end of each operating day, or at least once every 24 hours while disposal of RACM waste is occurring, the operator shall cover RACM waste that has been deposited at the landfill during the operating day or previous 24 hours with at least six inches of non-RACM material.

(e) For all RACM waste received, the owner or operator of the active landfill shall maintain in the operating record, waste shipment records that include the

(1) name, address, and telephone number of the waste generator;

(2) name, address, and telephone number of the transporter;

(3) amount of asbestos-containing waste material, measured in cubic yards; and

(4) date of receipt.

(f) The owner or operator of a landfill in which RACM waste has been disposed of shall maintain in the operating record, until the landfill closure is complete, a map or diagram showing the boundaries of the asbestos waste management area, its depth, and the amount, in cubic yards, of the RACM waste located there.

(g) Except as provided in (f) of this section, the owner or operator shall retain a copy of all records required under this section for at least two years, and shall furnish them to the department upon request.

(h) The owner or operator shall submit a workplan for approval at least 45 days before excavating or otherwise disturbing any asbestos-containing waste material that has been deposited at the landfill and covered. Department approval of the workplan is required before excavation may begin. If the excavation will begin on a date other than the one contained in the approved workplan, notice of the new date must be provided to the department at least 10 working days before excavation begins. Excavation may not begin earlier than the date specified in the approved workplan. A workplan submitted under this subsection must include the

(1) scheduled starting and completion dates;

(2) reason for disturbing the waste;

(3) procedures to be used to control emissions during the excavation, storage, transport, and ultimate disposal of the excavated asbestos-containing waste material;

(4) location of any temporary storage site; and

(5) final disposal site.

(i) At closure of a waste management area containing RACM waste, a final cover of at least two feet of non-asbestos-containing soil must be placed on the area and revegetated. A permanent survey marker must be constructed at the site. Drawings showing the boundaries of the RACM waste management area must be filed with the department and attached to the property deed, with a written warning about health and safety hazards related to disturbing the site. (Eff. 1/28/96, Register 137; am 7/11/99, Register 151)

Authority:	AS 44.46.020	AS 46.03.100	AS 46.06.080

18 AAC 60.455. Mining waste. Except when the only chemical being used is a flocculent to enhance settling, tailings from hard rock mines, and tailings from placer mines that have been amalgamated or chemically treated, are subject to 18 AAC 60.010 - 18 AAC 60.265, 18 AAC 60.400 - 18 AAC 60.495, 18 AAC 60.700 - 18 AAC 60.730, and 18 AAC 800 - 18 AAC 60.860 as necessary to prevent a violation of the air quality standards in 18 AAC 50 or the water quality standards in 18 AAC 70. The department will, in its discretion, incorporate applicable provisions of this chapter into a wastewater permit issued under 18 AAC 72 or a solid waste disposal permit issued under this chapter. (Eff. 1/28/96, Register 137; am 6/28/96, Register 138)

Authority:	AS 44.46.020	AS 46.03.020	AS 46.03.110
	AS 46.03.010	AS 46.03.100	AS 46.03.810

18 AAC 60.460. Inert waste. (a) The requirements of this section do not apply to a waste management area where inert waste is disposed of within the boundaries of a MSWLF.

(b) Liners are not required at an inert waste monofill.

(c) If a groundwater monitoring system is required at an inert waste monofill, under 18 AAC 60.820, detection monitoring under 18 AAC 60.840 and 18 AAC 60.850 during the active life of the monofill will be required only if the department

(1) determines that non-inert waste is or has been present at the site;

(2) detects evidence of a spill or groundwater contamination; or

(3) finds unexplained contamination in nearby wells.

(d) The owner or operator of an inert waste monofill who accepts combustible inert waste shall maintain fire control equipment and make it available to extinguish any fires that start.

(e) The owner or operator of an inert waste monofill shall construct a final cover of soil material at least 24 inches thick, graded to promote drainage without erosion, and shall revegetate it. The department will approve an alternate final cover design if the applicant demonstrates that the alternate design will protect public health, safety, and welfare, and the environment. After completion of the final cover on a monofill with a groundwater monitoring system, the owner or operator shall conduct detection monitoring at the frequency required by 18 AAC 60.850(b). (Eff. 1/28/96, Register 137; am 10/29/98, Register 148)

Authority: AS 44.46.020 AS 46.03.100 AS 46.03.800
AS 46.03.010 AS 46.03.110 AS 46.03.810
AS 46.03.020

18 AAC 60.470. Sewage solids. (a) The requirements of this section apply to the owner or operator of a sewage solids monofill. If a sewage solids monofill is located within the boundaries of a MSWLF, it is considered co-disposal with municipal solid waste, and the requirements of this section do not apply. If sewage solids are co-disposed of in a MSWLF, the owner or operator shall meet the requirements of 18 AAC 60.365.

(b) Waste placed in a sewage solids monofill must be dewatered and contain at least 10 percent solids by weight. Sewage or septage less than five percent solids by weight will be regulated as wastewater under 18 AAC 72. Sewage or septage that is five percent or more, but less than 10 percent, solids by weight may be handled as wastewater or dewatered to contain at least 10 percent solids by weight.

(c) If a sewage solids monofill does not have a liner and leachate collection system and the boundary of the monofill is

(1) 500 or more feet from the property line of the facility, sewage solids may not be disposed of in the monofill if they contain arsenic, chromium, or nickel in concentrations greater than

(A) the limits established in Table E of this subsection; or

(B) site-specific limits established under (d) of this section; or

manner that minimizes future settlement and instability. The surface of the industrial solid waste landfill may not be sloped more steeply than a 3:1 grade.

(d) The owner or operator of an industrial waste monofill shall install a final cover system designed and constructed to minimize

(1) infiltration through the closed landfill by use of an infiltration layer that contains at least 18 inches of earthen material with a permeability no greater than 1×10^{-5} centimeters per second; and

(2) erosion of the final cover by use of an erosion layer that contains at least six inches of earthen material capable of sustaining native plant growth.

(e) The department will approve an alternative to the final cover design required under (d) of this section if the applicant demonstrates that the proposed design

(1) will protect public health, safety, and welfare, and the environment; and

(2) includes

(A) an infiltration layer that achieves an equivalent reduction in infiltration as the infiltration layer specified in (d)(1) of this section; and

(B) an erosion layer that provides equivalent protection from wind and water erosion as the erosion layer specified in (d)(2) of this section. (Eff. 10/29/98, Register 148)

Authority: AS 44.46.020 AS 46.03.100 AS 46.03.810
AS 46.03.010 AS 46.03.110 AS 46.06.080
AS 46.03.020 AS 46.03.800

18 AAC 60.490. Closure demonstration and post-closure care. (a) After closure of a monofill, the owner or operator shall record a notation on the deed to the property of the facility, or some other instrument that is routinely examined during a title search. The owner or operator shall provide written notification to the department and the landowner that the notation has been recorded and that a copy has been placed in the operating record of the facility. The notation on the deed or other instrument must explain, in perpetuity, to any potential purchaser or leaseholder of the property

(1) that the land has been used as a monofill;

(2) the type of waste that was placed in the monofill;

(3) the geographical boundaries of the waste management areas; and

(4) details of any final cover, cap, or other structures or devices installed as part

of closure.

(b) The property owner may remove the notation required in (a) of this section from the deed or other instrument only if all wastes are removed from the property and the concentrations of any hazardous constituents then remaining do not exceed contemporary State of Alaska cleanup standards for contaminated sites.

(c) Except for a drilling waste disposal facility subject to 18 AAC 60.430(e)(2), the owner or operator of a monofill shall conduct visual monitoring, for settlement and erosion, for at least 60 consecutive months immediately following the closure. The department will require periodic visual monitoring at a monofill for up to 360 consecutive months immediately following the closure, if based on the type of waste and the site's compliance history under this chapter, the department determines that monitoring is necessary to protect the public health, safety, or welfare, or the environment. In addition to visual monitoring, the department will require groundwater, surface water, leachate, gas, and thermal monitoring at a monofill if the department finds that monitoring is necessary to protect the public health, safety, or welfare, or the environment. The department will also require additional monitoring and corrective action necessary to meet the standards in 18 AAC 60.815 and 18 AAC 60.860. The department will extend the post-closure monitoring period if necessary to ensure that the facility will not harm the public health, safety, or welfare, or the environment. At the end of the post-closure period, the owner or operator shall submit a report to the department that describes site conditions and summarizes the information collected during post-closure period. AS 46.03.020 AS 46.03.800

18 AAC 60.495. Permafrost conditions. Repealed. (Eff. 1/28/96, Register 137; repealed 9/7/2002, Register 163)

Article 7. Monitoring and Corrective Action Requirements.

Section
800. Visual and air monitoring
810. Surface water monitoring
815. Corrective action for problems discovered during visual and surface water monitoring or during an inspection
820. Groundwater monitoring and corrective action
825. Groundwater monitoring systems
830. Groundwater sampling and analysis
840. Parameters for surface water monitoring and groundwater detection monitoring
850. Detection monitoring program
860. Assessment monitoring and corrective action

18 AAC 60.800. Visual and air monitoring. (a) For a facility required to have a permit under 18 AAC 60.200, the permittee shall design a visual monitoring program to detect and document

(1) signs of damage or potential damage to any component of the facility from settlement, ponding, leakage, thermal instability, frost action, erosion, thawing of the waste, or operations at the facility;

(2) damage to the above-grade portions of groundwater monitoring devices or thermistors;

(3) violations of permit conditions or requirements of this chapter, specifically including the requirements in 18 AAC 60.225(a) that are readily observable;

(4) escape of waste or leachate or any unauthorized waste disposal;

(5) slippage of a flexible liner or damage to its anchor;

(6) erosion, a tear, a crack, or other damage to the visible portion of a liner;

(7) damage to the structural integrity of a containment structure, retaining wall, erosion control, or diversion structure;

(8) fire or combustion in the waste; and

(9) evidence of death or stress to fish, wildlife, or vegetation that might be caused by the facility.

(b) The department will require air pollution monitoring if there is credible evidence that the facility is causing or contributing to a violation of 18 AAC 50.

(c) The permittee shall ensure that a person who is familiar with permit requirements, with the applicable requirements of this chapter, and with the visual monitoring plan, conducts a visual inspection of the facility once each month, or at a frequency appropriate to facility operations as determined by the department and specified in the permit.

(d) The owner or operator shall keep records of visual monitoring conducted under this section with the operating record of the facility for at least five years after the visual monitoring was conducted. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148)

Authority: AS 44.46.020 AS 46.03.100 AS 46.03.810
AS 46.03.010 AS 46.03.110 AS 46.06.080
AS 46.03.020 AS 46.03.800

18 AAC 60.810. Surface water monitoring. (a) The department will require a surface water monitoring system at a facility if the department finds that surface water pollution is likely to endanger public health or cause a violation of the water quality standards in 18 AAC 70.

(b) If surface water monitoring is required under (a) of this section, surface water must be sampled at points of compliance selected by the permittee and approved by the department. The points of compliance must be chosen so that highest concentrations of hazardous constituents migrating off the facility will be detected and so that interference from sources of pollution unrelated to the facility's solid waste management operations will be minimized. The point of compliance will normally be located no more than 50 feet outside a waste management area boundary and on land owned by the owner of the facility. When establishing a point of compliance under this subsection, the owner or operator may, and the department will, consider the criteria of 18 AAC 60.825(c) that are applicable to surface water.

(c) If surface water monitoring is required under (a) of this section, points of compliance must be sampled during high flow and low flow conditions each year unless another schedule is approved or required by the department to meet the standards in (a) of this section.

(d) If surface water monitoring is required under (a) of this section, monitoring parameters will be selected by the department from those that are set out in 18 AAC 60.840. The department will approve alternative parameters that are indicative of the type of hazardous constituents associated with the type of waste handled at the facility.

(e) If surface water monitoring is required under (a) of this section, the owner or operator shall develop surface water monitoring procedures, including consistent sampling and analysis procedures designed to ensure that monitoring results provide an accurate representation of surface water quality at each location sampled. The owner or operator shall set out the procedures in a handbook or similar document and shall place the document in the operating record of the facility. The surface water monitoring procedures must include procedures and techniques for

(1) sample collection;

(2) sample preservation and shipment;

(3) analytical procedures;

(4) chain of custody control; and

(5) quality assurance and quality control.

(f) If surface water monitoring is required under (a) of this section, the owner or operator shall

(1) submit the results of surface water monitoring to the department after each sampling collection; and

(2) keep records of surface water monitoring conducted under this section with the operating record of the facility for at least five years after the monitoring was conducted.

(g) After a surface water monitoring program is established under this section, the owner or operator shall continue to comply with the surface water monitoring plan while the facility is active and throughout the monitoring period after the facility is closed. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148)

Authority:	AS 44.46.020	AS 46.03.070	AS 46.03.800
	AS 46.03.010	AS 46.03.100	AS 46.03.810
	AS 46.03.020	AS 46.03.110	

18 AAC 60.815. Corrective action for problems discovered during visual and surface water monitoring or during an inspection. (a) If a structural change in or damage to the facility or a monitoring device, or if a violation of a permit condition is observed during visual or surface water monitoring or during a department inspection, the owner or operator shall take action to correct the change, damage, or violation, to prevent the escape of waste or leachate, and to clean up waste that was disposed of in an unauthorized manner.

(b) If a statistically significant change in water quality is detected at the point of compliance as a result of the surface water monitoring program, the owner or operator shall

(1) determine the extent of contamination;

(2) determine if migration from the facility is the cause of the change in water quality;

(3) evaluate whether the water quality standards in 18 AAC 70 are threatened or exceeded at the point of compliance selected under 18 AAC 60.810; and

Article 8. General Provisions.

Section
900. Waivers
990. Definitions

18 AAC 60.900. Waivers. (a) Subject to (b) of this section, the department will grant a waiver of one or more provisions of this chapter, except a provision applicable to a Class I MSWLF and required by 40 C.F.R. 258, revised as of July 1, 1998. To secure a waiver under this section, the applicant must identify, in writing, the provision sought to be waived and must demonstrate that

(1) compliance with the identified provision would cost significantly more than the value of the environmental benefit, public health risk reduction, and nuisance avoidance that could be achieved through compliance with the identified provision; or

(2) the proposed alternative action will provide equal or better environmental protection, reduction in public health risk, and control of nuisance factors than compliance with the identified provision.

(b) In granting a waiver, the department will impose specific conditions as necessary to assure that public health and welfare and the environment are protected. (Eff. 1/28/96, Register 137; am 7/11/99, Register 151)

Authority: AS 44.46.020 AS 46.03.010 AS 46.03.020

18 AAC 60.990. Definitions. Unless the context indicates otherwise, in this chapter

(1) "accepts for disposal" means the act of

(A) accepting solid waste at a solid waste disposal facility and then disposing of the waste without treating the waste; or

(B) disposing of waste or residue that is left after solid waste has been incinerated or otherwise treated;

(2) "accumulation" means the collection of waste or discarded material until the waste or material can be shipped for disposal or another use;

(3) "active life" means the period of operation beginning with the first receipt of solid waste and ending at completion of closure activities;

(4) "active portion" means that part of a facility or unit in which disposal

operations have been or are being conducted, but does not include a facility or unit with a complete final cover;

(5) "active thaw zone" means the surface layers of organic matter and mineral soils that thaw each year in areas of permafrost;

(6) "agronomic rate for nitrogen" means the maximum amount of nitrogen-containing material that can be spread evenly over an area so that all of the nitrogen in the material is used by the crops grown onsite, taking into account any residual nitrogen present in the soil or the addition of another fertilizer;

(7) "airport" means a public-use airport open to the public without prior permission and without restrictions within the physical capacities of available facilities;

(8) "amalgamated" means to mix or alloy a metal with mercury;

(9) "animal waste" means discarded material originating from an animal inoculated with an infectious agent during research, production of biologicals, or pharmaceutical testing; "animal waste" includes the carcass, body parts, blood, and bedding of any animal known to have been in contact with an infectious agent;

(10) "application site" means a facility subject to land application of sewage solids or biosolids;

(11) "approved" means approved by the department;

(12) "aquifer" means a geological formation, group of formations, or portion of a formation capable of yielding significant quantities of groundwater to wells or springs;

(13) "aquifer of resource value" means an area beneath the ground that is used as a drinking water supply source, has a reasonable potential to be used as a drinking water supply source, or has some other potential use for which uncontaminated water might be important;

(14) "area susceptible to mass movement" means an area of influence, including an area characterized as having an active or substantial possibility of mass movement, when the movement of earth material at, beneath, or adjacent to a MSWLF, because of natural or human-induced events, results in the downslope transport of soil and rock material by means of gravitational influence, including landslides, avalanches, debris slides and flows, soil fluction, block sliding, and rock fall;

(15) "asbestos" means the asbestiform varieties of serpentine (chyrsotile), riebeckite (crocidolite), cummingtonite-grunerite, anthophyllite, and actinolite-tremolite;

(16) "aufeis" means ice that is formed as water flows over a frozen surface;

(17) "barrier berm" means an above-grade containment structure used in regions of continuous permafrost;

(18) "barrier layer" means a continuous horizontal layer of natural or synthetic materials through which the movement of liquid is prevented or greatly restricted;

(19) "base flood" means a flood that has a one percent or greater chance of recurring in any year, or a flood of a magnitude equaled or exceeded once in 100 years on the average over a significantly long period;

(20) "biosolids" means solid, semi-solid, or liquid residue generated during treatment of domestic sewage in a treatment works; "biosolids" includes domestic septage; scum or solids removed in primary, secondary, or advanced wastewater treatment processes; and a material derived from biosolids; "biosolids" does not include ash generated during the firing of biosolids in a biosolids incinerator or grit and screenings generated during preliminary treatment of domestic sewage in a treatment works;

(21) "bird hazard" means an increase in the likelihood of a bird-aircraft collision that might cause damage to the aircraft or injury to its occupants;

(22) "blood and blood products" means discarded waste human blood and blood components, including serum and plasma, and materials containing free-flowing blood and blood components;

(23) "cap" means a combination of natural or synthetic materials, including a barrier layer and final cover, placed on a closed waste containment structure;

(24) "Category I nonfriable asbestos-containing material" means asbestos-containing packings, gaskets, resilient floor covering, and asphalt roofing products that contain more than one percent asbestos, determined using the method in 40 C.F.R. 763, Subpart E, Appendix E, Polarized Light Microscopy, revised as of July 1, 1997, adopted by reference;

(25) "Category II nonfriable asbestos-containing material" means asbestos-containing material such as shingles, wallboard, or cementitious pipe that

(A) contain more than one percent asbestos, determined using the method in 40 C.F.R. 763, Subpart E, Appendix E, Polarized Light Microscopy, revised as of July 1, 1997, adopted by reference; and

(B) when dry, cannot be crumbled, pulverized, or reduced to powder by hand pressure;

(26) "Clean Water Act" means the "Federal Water Pollution Control Act," 33 U.S.C. 1251 - 33 U.S.C. 1387, as amended through August 21, 1998;

(27) "closed portion" means that part of a facility or unit that has been closed in accordance with this chapter;

(28) "commercial solid waste" means all types of solid waste generated by a store, office, restaurant, warehouse, or other nonmanufacturing activity; "commercial solid waste" does not include residential and industrial wastes;

(29) "containment structure" means a type of waste management area in which an arrangement of dikes, walls, barrier berms, pits, ice storage pits, liners, pads, cover material, and other similar constructs are used to hold solid waste and to prevent the escape, seepage, or discharge of solid waste and leachate from, or infiltration of water or precipitation into, the waste management area;

(30) "cover material" means a natural or synthetic material, or combination of materials, used to cover solid waste disposed of at a solid waste disposal facility or unit;

(31) "crumb rubber" means vehicle tires that have been chopped and ground to a grain size less than or equal to one-quarter inch in diameter;

(32) "crystallization point" means the temperature below 32 F at which ice crystals begin to form;

(33) "cultures and stocks" means discarded cultures and stocks of infectious agents and associated microbiologicals, including human and animal cell cultures from medical and pathological laboratories, cultures and stocks of infectious agents from research and industrial laboratories, waste from the production of biologicals, discarded live and attenuated vaccines, and culture dishes and devices used to transfer, inoculate, or mix cultures of infectious agents;

(34) "demonstrate" means to make a showing of fact to the department; unless a different standard is established on a case-by-case basis, a "demonstration" required by this chapter must show the asserted conclusion by a preponderance of evidence;

(35) "department" means the Alaska Department of Environmental Conservation;

(36) "designated portion" means the active portion of a facility, including the closed portion and that portion set aside to become an active portion in the future;

(37) "disease vector" means a carrier that can transmit a pathogen from one organism to another, and includes flies and other insects, rodents and other small mammals, birds, and vermin;

(38) "displacement" means the relative movement of any two sides of a fault, measured in any direction;

(39) "disposal" means the deposit of a solid or liquid waste into or onto the water or land of the state, whether the waste is contained or uncontained, by discharging, injecting, dumping, spilling, leaking, placing, discarding, or abandoning the waste so that the waste or any part or byproduct of the waste might enter the environment;

(40) "domestic wastewater" has the meaning given in 18 AAC 72.990;

(41) "drilling waste" means exploration and production waste exempted from RCRA Subtitle C that is associated with the exploration, development, or production of crude oil, natural gas, or geothermal energy; "drilling waste" includes drilling muds, cuttings, hydrocarbons, brine, acid, sand, and emulsions or mixtures of fluids produced from and unique to the operation or maintenance of a well, whether naturally occurring or added for the operation or productivity of the well; "drilling waste" is only waste described in this paragraph that is derived intrinsically from primary field operations, produced from a well, and removed at the drill site or removed at a crude oil production facility by crude oil or wastewater treatment process before custody transfer of the crude oil; "drilling waste" does not include spent solvents and oils from equipment maintenance activities, discarded chemical products, or fuels;

(42) repealed 9/7/2002;

(43) "emergency relief volume" means the space necessary to contain material expelled from an oil or gas well during an underground pressure imbalance; the minimum emergency relief volume is routinely one and one-half times the well bore or casing volume;

(44) "EPA" means the United States Environmental Protection Agency;

(45) "existing MSWLF" means a municipal solid waste landfill that was receiving solid waste as of October 9, 1993;

(46) "existing or developing population" means a community of persons residing in close proximity to each other, with a concentration equivalent to at least 120 persons per one-quarter section (160 acres);

(47) "explosive gas" means methane (CH_4);

(48) "facility" means all contiguous land and structures, other appurtenances, and improvements on land used for treatment, storage, or disposal of solid waste; facility includes solid waste disposal facilities, solid waste processing facilities, and treatment works;

(49) "facility structures" means any buildings, sheds, or utility or drainage lines on the facility;

(50) "fault" means a fracture or a zone of fractures in any material along which strata on one side have been displaced with respect to that on the other side;

(51) "floodplain" means the lowland and relatively flat areas adjoining inland and coastal waters; "floodplain" includes flood-prone areas of offshore islands, that are inundated by the 100-year flood; for purposes of this paragraph, "100-year flood" means a flood that has a one percent or greater chance of recurring in any given year or a flood of a magnitude equalled or exceeded once in 100 years on the average over a significantly long period;

(52) "fluid management plan" means the use of snow removal or any dewatering practice to keep to a minimum the hydrostatic head of fluids and drilling wastes in a containment

structure; "fluid management plan" includes approved disposal of liquid wastes in an injection well, or by other approved discharge to the land and water of the state;

(53) "freezeback" means the process of freezing solid waste in place as a means to prevent the migration of solid waste and leachate from the designated portion of a facility or unit;

(54) "friable asbestos material" means material that

(A) contains more than one percent asbestos, determined using the method in 40 C.F.R. 763, Subpart E, Appendix E, Polarized Light Microscopy, revised as of July 1, 1997, adopted by reference; and

(B) when dry, can be crumbled, pulverized, or reduced to powder by hand pressure;

(55) "gas condensate" means the liquid generated as a result of a gas recovery process at a MSWLF;

(56) "groundwater" means water below the land surface in the zone of saturation;

(57) "hard rock mine" means a mining facility, on the surface or underground, in which mineral resources are extracted from consolidated or lithified geologic formations;

(58) "hazardous constituent" means a constituent listed in 40 C.F.R. Part 258, Appendices I or II, revised as of July 1, 1997;

(59) "hazardous waste" has the meaning given in AS 46.03.900;

(60) "Holocene" means the most recent epoch of the Quaternary period, extending from the end of the Pleistocene Epoch to the present; "Holocene" is generally considered to be 10,000 years;

(61) "household waste" means solid waste; "household waste" includes garbage, trash, and sanitary waste in septic tanks, derived from a household; for the purposes of this paragraph, "household" includes single and multiple residences, hotels and motels, bunkhouses, ranger stations, crew quarters, campgrounds, picnic grounds, and day-use recreation areas;

(62) "inactive reserve pit" means a drilling waste disposal area, containment structure, or group of containment structures where drilling waste has not been disposed of after January 28, 1996 and at which the owner or operator does not plan to dispose of drilling waste;

(63) "industrial solid waste" means solid waste generated by a manufacturing or industrial process that is not a hazardous waste regulated under 42 U.S.C. 6921 - 42 U.S.C. 6939b (RCRA, Subtitle C), as amended through August 21, 1998; "industrial solid waste" includes polluted soil, inorganic chemicals, iron and steel manufacturing waste, leather and leather products, waste from nonferrous metals manufacturing and foundries, drilling waste, organic chemicals, plastic resin waste, sludges and boiler ash from the pulp and paper industry,

rubber and miscellaneous plastic products, textile manufacturing waste, and water treatment chemicals; "industrial solid waste" does not include coal ash, slaughterhouse waste, wood waste, inert waste, or mining waste;

(64) "inert waste" means solid waste that has a low potential to pollute air or water, and that does not normally attract wildlife; "inert waste" includes coal power plant ash, scrap metal, auto fluff, construction and demolition waste, and pavement rubble; "inert waste" does not include asphalt material that contains asbestos;

(65) "injection well" means a confined subsurface porous soil or rock formation for the disposal of waste;

(66) "karst terrane" means an area where karst topography, with its characteristic surface and subterranean features, is developed as the result of dissolution of limestone, dolomite, or other soluble rock; in this paragraph "characteristic surface and subterranean features" include sinkholes, sinking streams, caves, large springs, and blind valleys;

(67) "landfill" means an area of land, or an excavation in which solid wastes are placed for permanent disposal, and that is not an application site, injection well, reserve pit, or waste pile;

(68) "lateral expansion" means a horizontal expansion of the waste boundaries of an existing solid waste disposal facility;

(69) "leachate" means liquid that has passed through or emerged from solid waste and contains soluble, suspended, or miscible materials removed from the wastes;

(70) "leachate collection system" means a system or device installed immediately above a liner that is designed, constructed, maintained, and operated to collect and remove leachate from a landfill;

(71) "liner" means a continuous layer of natural or synthetic materials beneath or on the sides of a landfill or solid waste containment structure, or a vertical layer installed in a barrier berm, that extends continuously from the base of the active thaw zone to the top of the barrier berm to prevent solid waste and leachate from escaping from the landfill or the containment structure;

(72) "liquid waste" means waste material that is determined to contain free liquids as defined by Method 9095 (Paint Filter Liquids Test), as described in *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods* (SW-846), adopted by reference in 18 AAC 60.365;

(73) "lithified earth material" means rock, including naturally occurring and naturally formed aggregates or masses of minerals or small particles of older rock that formed by

crystallization of magma or by induration of loose sediments; "lithified earth material" does not include human-made material, such as fill, concrete, and asphalt, or unconsolidated earth material, soil, or regolith lying at or near the earth surface;

(74) "litter" has the meaning given that term in AS 46.06.150;

(75) "lower explosive limit" means the lowest percent by volume of a mixture of explosive gases that will propagate a flame in air at 25°C and atmospheric pressure;

(76) "major road system" means a system of connected pioneer roads and community roads as described in 17 AAC 05.030, with a total length of 100 miles or more;

(77) "maximum horizontal acceleration in lithified earth material" means the maximum expected horizontal acceleration depicted on a seismic hazard map, with a 90 percent or greater probability that the acceleration will not be exceeded in 250 years, or the maximum expected horizontal acceleration based on a site-specific seismic risk assessment;

(78) "medical waste" means laboratory waste consisting of discarded cultures and stocks of infectious agents and associated microbiologicals; pathological wastes; selected isolation waste; used and unused discarded sharps; animal waste; human blood, or blood products; and other wastes defined as "regulated waste" in 29 C.F.R. 1910.1030(b), revised as of July 1, 1997;

(79) "medical waste incinerator" means

(A) a two-chambered incinerator that holds waste for at least one second at temperatures at or above 1700°F in the secondary chamber, and operates at 1200° or more in the primary chamber; or

(B) a thermal oxidation unit approved by the department;

(80) "monofill" means a landfill or drilling waste disposal facility that receives primarily one type of solid waste and that is not an inactive reserve pit;

(81) "MSWLF" means a municipal solid waste landfill;

(82) "municipal solid waste landfill" and "MSWLF" mean an area of land or an excavation that receives household waste, and that is not an application site, surface impoundment, injection well, or waste pile; "municipal solid waste landfill" includes a new MSWLF, an existing MSWLF, and a lateral expansion of an existing MSWLF;

(83) "new MSWLF" means a municipal solid waste landfill unit that did not receive waste before October 10, 1993;

(84) "nondomestic wastewater" has the meaning given in 18 AAC 72.990;

(85) "nonfriable asbestos material" means asbestos-containing material that, when dry, cannot be crumbled, pulverized, or reduced to powder by hand pressure;

(86) "open burning" means the combustion of solid waste without

(A) control of combustion air to maintain adequate temperature for efficient combustion;

(B) containment of the combustion reaction in an enclosed device to provide sufficient residence time and mixing for complete combustion; and

(C) control of the emission of the combustion products;

(87) "operator" means the person or persons responsible for the overall operation of a facility;

(88) "owner" means the person or persons who own a facility; unless expressly excluded in a particular section, "owner or operator" includes the holder of a permit issued under this chapter regardless of whether the permittee otherwise fits within the definitions given of those terms;

(89) "pathological waste" means discarded pathological waste, including human tissues, organs, and body parts removed during surgery, autopsy, or other medical procedure;

(90) "PCB waste" means polychlorinated biphenyls waste;

(91) "permafrost" means soil in which the naturally occurring temperature has remained below 32°F for two or more consecutive years;

(92) repealed 9/7/2002;

(93) "permanently frozen state" means the condition at which both of the following occur:

(A) the temperature of the waste is perpetually at or colder than 0.5 degrees F below the crystallization point of the waste; and

(B) migration of leachate and other waste constituents from the buried waste is prevented;

(94) "pH" means the logarithm of the reciprocal of the hydrogen ion concentration;

(95) "placer mining" means obtaining, by washing or dredging, minerals from a glacial or alluvial deposit of sand or gravel that contains eroded particles of valuable minerals;

(96) "polluted run-off water" means water that violates a criterion of 40 C.F.R.

257-3-3, revised as of July 1, 1997, adopted by reference, the water quality standards of 18 AAC 70, or the drinking water standards of 18 AAC 80;

(97) "polluted soil" means

(A) soil that is placed into a landfill, that is not a regulated hazardous waste, and that was excavated during a spill response or leaking underground storage tank action or to comply with an approved contaminated site cleanup plan under 18 AAC 75 or 18 AAC 78; or

(B) a residue or other material that is placed into a landfill and that is not a regulated hazardous waste but contains a hazardous substance in a concentration exceeding the applicable soil cleanup levels set out in 18 AAC 75.341, Table B1 or Table B2;

(98) "pollution" has the meaning given in AS 46.03.900;

(99) "poor foundation conditions" means an area where features exist that indicate a natural or human-induced event might result in inadequate foundation support for the structural components of a solid waste disposal facility;

(100) "Portland cement" means a material used primarily as the ingredient that binds the aggregate together in concrete; concrete made with Portland cement differs from asphalt cement in that Portland cement hardens due to the hydration of lime, while asphalt cement, which uses hydrocarbons as a binder, hardens as it cools;

(101) "public water system" means a source of water, intake works, collection system, treatment works, storage facility, or distribution system from which water is available for human consumption; "public water system" includes systems providing water to more than one residential dwelling unit, or to a factory, office building, restaurant, school, or other similar facility, "public water system" does not include a system serving only a single-family residence;

(102) "pumpable fluids" means fluids that can be readily pumped or made to flow under normal conditions at temperatures above freezing;

(103) "putrescible waste" means solid waste that contains organic matter capable of being decomposed by microorganisms and of such a character and proportion as to cause obnoxious odors and to be capable of attracting or providing food for birds or animals;

(104) "qualified groundwater scientist" means a scientist or engineer who has received a baccalaureate or post-graduate degree in the natural sciences or engineering and has sufficient training and experience in groundwater hydrology and related fields as may be demonstrated by professional certification or completion of accredited university programs that enable that scientist or engineer to make sound professional judgments regarding groundwater monitoring, contaminant fate and transport, and corrective action;

(105) "RCRA" means the Resource Conservation and Recovery Act, 42 U.S.C. 6901 - 42 U.S.C. 6992k, as amended through August 21, 1998;

(106) "recycling" means the process by which a material that would otherwise be destined for disposal is collected, reprocessed, or remanufactured, and then reused;

(107) "registered engineer" means an engineer who is registered in this state under AS 08.48.211;

(108) "regulated asbestos-containing material or RACM" means

(A) friable asbestos material;

(B) Category I nonfriable asbestos-containing material that has become friable;

(C) Category I nonfriable asbestos-containing material that will be, or has been, subject to sanding, grinding, cutting, or abrading; and

(D) Category II nonfriable asbestos-containing material that has a high probability of becoming, or has become, crumbled, pulverized, or reduced to powder by the forces expected to act on the material in the course of a demolition or renovation operation regulated by 40 C.F.R. 61.145, revised as of July 1, 1997, or in the course of a disposal operation regulated under this chapter;

(109) "regulated hazardous waste" means a waste that is a hazardous waste, as defined in 40 C.F.R. 261.3, revised as of July 1, 1998, adopted by reference, that is not excluded from regulation as a hazardous waste under 40 C.F.R. 261.4(b), revised as of July 1, 1998, adopted by reference, and was not generated by a conditionally exempt small quantity generator;

(110) "reinforced barrier berm" means a barrier berm in which a liner is installed;

(111) "representative sample" means a sample the chemical makeup or characteristics of which are indicative of the in situ material from which it came;

(112) "resource recovery" means the recovery of materials or energy from solid waste for industrial use, agriculture, heat production, power production, or another process or purpose, including recycling;

(113) "road base" means the areas under and adjacent to the surface of a road that are not normally in contact with standing water;

(114) "run-off" means rainwater, leachate, or other liquid that drains over land from any part of a facility;

(115) "run-on" means rainwater, leachate, or other liquid that drains over land onto any part of a facility;

(116) "salvaging" means the controlled removal of waste materials for recycling or reuse;

(117) "seismic impact zone" means an area with a 10 percent or greater probability that the maximum horizontal acceleration in lithified earth material, expressed as a decimal fraction of the earth's gravitational pull will exceed 0.10g in 250 years;

(118) "selected isolation waste" means discarded waste material that is contaminated with excretions, exudates, and secretions from patients with highly communicable diseases, and that is treated in isolation; "selected isolation waste" includes blood and blood components, and sharps;

(119) "septage" means liquid or solid material removed from a septic tank, cesspool, portable toilet, Type III marine sanitation device, or similar treatment works that receives only domestic sewage; "domestic sewage" does not include liquid or solid material removed from a septic tank, cesspool, or similar treatment works that receives commercial wastewater or industrial wastewater and does not include grease removed from a grease trap at a restaurant;

(120) "sewage solids" means waste that passes the paint filter test (EPA Test Method 9095, published in Test Methods for Evaluating Solid Waste, Physical/Chemical Methods (SW-846), adopted by reference in 18 AAC 60.365, and has been removed from a wastewater treatment system, sewer, septic tank, or other wastewater handling equipment; "sewage solids" includes lagoon dredge, sewer cleanout waste, barscreen grit, and wastewater treatment sludge;

(121) "sewage solids monofill" means a monofill used for disposal of sewage solids, including a "surface disposal site" as defined in 40 C.F.R. 503.21, revised as of July 1, 1997;

(122) "sharps" means discarded implements or parts of equipment used in animal or human patient care, medical research, or industrial laboratories, including hypodermic needles, syringes, pasteur pipettes, scalpel blades, blood vials, needles with attached tubing, broken or unbroken glassware that has been in contact with an infectious agent, slides, cover slips, and unused, discarded implements or parts of equipment;

(123) "site" means the land, structures, and equipment at a given location associated with a facility subject to this chapter;

(124) "solid waste" has the meaning given in AS 46.03.900;

(125) "solid waste disposal facility" has the meaning given in AS 46.03.900;

(126) "solid waste management system" means a comprehensive waste management regime that might extend beyond the boundary of a single facility, "solid waste management system" includes transport, storage, treatment, and disposal operations;

(127) "solid waste processing facility" has the meaning given in AS 46.03.900;

(128) "spoil and overburden" means soil, rock, and other material that is removed during a mining operation to gain access to ore;

(129) "store" means holding for a temporary period, at the end of which the material being held is treated, disposed of, or otherwise relocated;

(130) "structural component" means a liner, leachate collection system, final cover, run-on/run-off system, and any other component used in the construction and operation of a waste management area that is necessary to protect public health, safety, and welfare and the environment;

(131) "surface impoundment" or "impoundment" means a facility or part of a facility that is a natural topographic depression, human-made excavation, or diked area formed primarily of earthen materials, although it may be lined with human-made materials, that is designed to hold an accumulation of liquid wastes or wastes containing free liquids and that is not an injection well; "surface impoundments" includes holding storage, settling, and aeration pits, ponds, and lagoons;

(132) "surface transportation" means pioneer roads and community roads as described in 17 AAC 05.030, or a railroad system that routinely handles freight; "surface transportation" does not include barges or any other form of water craft;

(133) "surface water" means water

(A) open to the atmosphere and subject to surface run-off; and

(B) from springs, wells, or other collectors directly influenced by surface water;

(134) "tailings" means refuse or dross remaining after ore from a mining operation has been processed;

(135) "thermal instability" means the potential for subsurface degradation of the soils due to thawing in permafrost or ice-rich areas;

(136) "transfer station" means a public use facility for the deposit and temporary storage of solid waste, "transfer station" includes a transfer station located at a landfill; "transfer station" does not include a facility for the storage of a regulated hazardous waste;

(137) "treat" means subjecting waste to physical, mechanical, chemical, biological, or thermal processes that reduce the volume or toxicity, or change the characteristics of the waste;

(138) "treatment works" has the meaning given in AS 46.03.900;

(139) "twenty-five-year storm" or "25-year storm" means a storm that has no

more than a four percent chance of recurring in any given year or a storm of magnitude equaled or exceeded once in 25 years on the average over a significantly long period;

(140) "Type I error" means in a statistical test, incorrectly indicating pollution or an increase in pollution;

(141) "unsaturated zone" means the ground layer beneath the topsoil and overlying the water table in which water in the pore spaces coexists with air or in which geological matter is unsaturated;

(142) "unstable area" means a location that is susceptible to natural or human-induced events or forces capable of impairing the integrity of some or all of a landfill's structural components responsible for preventing releases from the landfill; "unstable area" includes poor foundation conditions, areas susceptible to mass movements, or earthquake-induced failures, areas underlain by permafrost, and Karst terranes;

(143) "uppermost aquifer" means the geologic formation nearest the natural ground surface that is an aquifer, as well as lower aquifers that are hydraulically interconnected with this aquifer within, or immediately downgradient of, the facility's boundary;

(144) "washout" means the carrying away of solid waste by waters of the base flood;

(145) "waste disposal permit" means a permit issued under this chapter;

(146) "waste incompatible with freezeback" means waste that prevents the buried waste in a landfill from attaining a permanently frozen state within the time period allowed in a permit issued under this chapter;

(147) "waste management area" means that part of a facility in which solid wastes are treated, stored, or disposed of;

(148) "waste management boundary" means a plane surface located at the hydraulically downgradient limit of a waste management area, extending down into the uppermost aquifer;

(149) "waste pile" or "pile" means any noncontainerized accumulation of solid, nonflowing waste;

(150) "waste rock" means rock that has been removed during mining or advanced exploration that does not contain sufficient metallic minerals to constitute ore; "waste rock" includes spoil and overburden;

(151) "waste source reduction" means a change in a habit or process that results in less waste being produced, "waste source reduction" does not include physical processing of

waste in balers or incinerators;

(152) "water" or "waters" has the meaning given in AS 46.03.900;

(153) "wetlands" has the meaning given in 40 C.F.R. 232.2, revised as of July 1, 1997;

(154) "wood waste" means a solid waste that is generated during the transfer or processing of timber, "wood waste" includes wood chips, bark, sawdust, and other such woody debris;

(155) "large inert landfill" means a landfill that is designed to accept more than 1000 cubic yards of inert waste;

(156) "institutional control" means a measure taken to limit, prohibit, or protect against an activity that could

(A) interfere with the integrity of activities or improvements designed to encapsulate or control pollution at a facility, or

(B) result in human or environmental exposure to pollution;

(157) "acute hazardous waste" means a waste identified as an acute hazardous waste under 40 C.F.R. 261.30 – 261.33, revised as of July 1, 1998, adopted by reference;

(158) "conditionally exempt small quantity generator" has the meaning given in 40 C.F.R. 261.5, revised as of July 1, 1998, adopted by reference;

(159) "post closure period" means the time period following closure of a facility during which monitoring or care of the facility is required under this chapter; if a closure report or certification is required, the post-closure period begins when the report or certification requirements is satisfied and ends when the conditions of 18 AAC 60.270 are met;

(160) "food waste disposal facility" means a facility used to dispose of

(A) slaughterhouse waste;

(B) waste from a seafood processing facility subject to 18 AAC 34; or

(C) waste from a food processing establishment subject to 18 AAC 31;

(161) Repealed 09/5/2010;

(162) "household hazardous waste" means solid waste that may have hazardous constituents, but that is not regulated under 42 U.S.C. 6921 – 6939e (resource Conservation and Recovery Act, subtitle C) because it is generated by a household; for purposes of this paragraph, "household" includes single and multiple residences, hotels and motels, bunkhouses, ranger

stations, crew quarters, campgrounds, picnic grounds, and day-use recreation areas;

(163) "household hazardous waste storage facility" means a facility used for the collection or storage of

(A) household hazardous waste; or

(B) conditionally exempt small quantity generator waste that is not regulated under 42 U.S.C. 6921 – 6939e (Resource Conservation and Recovery Act, subtitle C) if disposed of in accordance with those provisions;

(164) "untreated medical waste" means medical waste that has not been treated in an autoclave according to the manufacturer's instructions or incinerated;

(165) "wetted surface" means that area of a solid waste disposal cell or trench excavation surface that is in contact with solid or liquid waste;

(166) "working day" means a day other than Saturday, Sunday, or a state holiday. (Eff. 1/28/96, Register 137; am 10/29/98, Register 148; am 7/11/99, Register 151; am 6/30/2002, Register 162; am 9/7/2002, Register 163; am 9/5/2010, Register 195; am 4/12/2013, Register 206)

INERT WASTE MONOFILL
SOLID WASTE PERMIT APPLICATION

PART SEVEN- OPERATIONS PLAN

Central Monofill Services, Inc
Palmer, Alaska

January 2013

Matanuska - Susitna Borough
Development Services

MAY 1 4 2014

Received

Permit: *Alaska DEC, Solid Waste Program*
Applicant: *Central Monofill Services, Inc.*
Date Submitted: *January 8, 2013*

Central Monofill Services Inc.'s Inert Waste Monofill Permit
Part Seven- Operations Plan

Location(s): Milepost 35.3 Glenn Highway, Palmer Alaska 99645
Owner: CMS Inc.
Operator: CRS Inc.
Tax ID(s): 18N02E18C010

The information in this document is an attachment to Central Monofill Services Incorporated's (hereafter known as CMS's) DEC Inert Waste Monofill Permit Application, Part Seven - Operations Plan.

For any questions, comments or clarifications, please do not hesitate to contact myself, Shane Durand.

Should there be any changes or amendments needed for this Inert Waste Monofill Applications, all edits will be made in writing and submitted to the Alaska Department of Environmental Conservation, Division of Environmental Heath, Solid Waste Program in a timely fashion.

Sincerely,

Shane Durand
Secretary/Treasurer

***Permit:** Alaska DEC, Solid Waste Program*
***Applicant:** Central Monofill Services, Inc.*
***Date Submitted:** January 8, 2013*

Project Description

CMS's goal for this Inert Waste Monofill, is to have Central Recycling Service, Inc. (CRS) properly place and cover inert debris on a portion of the property, while maintaining and reclaiming a 120 acre site located on Lot C10, Located in Township 17 North, Range 2 East, Section 18 and Lot B6, Located in Township 17 North, Range 2 East, Section 19 in Palmer, Alaska 99645.

Lot C10 is in the South West corner of Section 18 and B6 Adjacent just South of C10. The site has historically been used as a Gravel Pit. The site contours very greatly as different sections of the lot have been mined for gravel. The surrounding slopes are at the natural angle of repose for the material, in some cases as steep as 2:1 (See Attached Plan set, Sheet 1, Existing Conditions). This monofill will occupy 35.4 acres in the southwest corner of the lot C10 and all of Lot B6 north of the Glenn Highway and maintain a 100' buffer from the existing gravel ponds located on the lot C10. The groundwater at the site varies across the site with water elevations close to 85 feet in the northeast corner and down to 70 feet in the south corner. The depth to ground water at specific locations varies significantly due to the widely varying terrain at the site.

The site has been traditionally used as a gravel pit, so the soils onsite vary from some well graded, sandy gravel material to areas of unusable for mining materials such as clay and silt. The industrial ponds onsite are as deep as 80 feet. Permafrost has not been encountered at any time on site during historical use and the area of Palmer is in a sporadic permafrost zone so the likelihood of permafrost at this site is low. Due to the composition of soil containing well graded gravel, the percolation rate at the site is moderate to high. The nearest water bodies are the three industrial ponds onsite. They are manmade industrial ponds caused by past gravel dredging. These bodies do not have inflowing or outflowing water and are fed from onsite surface flow and groundwater. The Matanuska River lies approximately 2 miles to the southeast and this river ultimately discharges into the ocean in the Knik Arm approximately 4.5 Miles southwest.

Access Control

The driveway for Lot C10 is located off of the Glenn Highway and currently has a two driveway configuration that will be used as an entrance/exit configuration. It is the only access point for the inert debris monofill on the site. Signage will be posted informing the public of the monofill operation, private property, not to trespass and/or not to enter the site unless authorized or accompanied by authorized personnel. This access point will prevent unsolicited visitors to trespass onsite (pedestrians/target practice/off-road vehicle usage) and away from any site activities. There will also be a gate and fence that extends up the natural berm surrounding the entrance.

The driveway is currently permitted through DOT&PF since the driveway extends into the Glenn Highway ROW.

***Permit:** Alaska DEC, Solid Waste Program*
***Applicant:** Central Monofill Services, Inc.*
***Date Submitted:** January 8, 2013*

Seasonal Start and End Dates

This site will be operated year round.

Hours of Operations / Days of the Week

The operational hours will generally be from 7am to **7pm, Monday through Saturday.**

Waste Acceptance and Handling Policy

The inert debris brought to this site will be primarily shredded residual, recycling waste, material. Shredded residual material is a variety of non-hazardous, inert material which is shredded to a size of 12 inches or smaller. This material is the by-product of a recycling facility located in Anchorage, Alaska called Central Recycling Services. Central Recycling Services (CRS) specializes in recycling inert construction and demolition waste. The material brought to CRS is both manually and mechanically sorted, screened and processed through to ensure the material is free of hazardous material, putrescible material and/or liquids. The shredded inert material will be placed in a trailer and used as the inert debris for this monofill

Material that will not be accepted at this monofill location will be as follows:

- **PCBs or other Hazardous Wastes**
- **Household Waste**
- **Putrescible Waste**
- **Liquids**
- **Compressed Gas Cylinders**
- **Batteries**
- **Appliances with CFC/HCFC**
- **Chemical Waste**
- **Animal Carcasses**
- **Petroleum Contaminated Materials**

It is Central Recycling Services' policy to require additional documentation from all material haulers transporting any demolition and/or renovation material to the Central Recycling Services' Facility.

The additional information required is: (1) A copy of all Hazardous Building Material Surveys for each project that will be bringing their demolition and/or renovation material to the Central Recycling Facility. Should the Survey indicate the presence of any hazardous materials, then (2) A letter from the Contractor of each project is also to be submitted to Central Recycling Services stating that all hazardous material have been properly removed from the project, and there is no hazardous material being brought to the Central Recycling Facility. For their operations, CRS defines hazardous material as a material containing any percentage of asbestos.

Any demolition and/or renovation material brought to the CRS Facility is not allowed to be dumped onto the Tipping Floor until both of the above mentioned documents have been provided to and reviewed by the authorized CRS employees. When delivered, any material identified in the survey will be searched for within the waste.

Please note that CRS is not open to the public. All customers/haulers are pre-approved and have signed credit applications including indemnity. By signing this document, they acknowledge that hazardous material is not accepted at the CRS Facility.

These policies in place at CRS will help to reduce the risk of prohibited items or contaminates from reaching the monofill.

Although the CRS residual material is the primary material to be deposited at the monofill some inert material will be hauled directly to the monofill without being processed at the CRS recycle facility. These materials will require the same documentation and have the same scrutiny as those delivered directly to CRS.

Fire Mitigation Procedures

Exothermic reactions have been shown to be problems in landfills that accept organic materials. Exothermic reactions occur when organic materials are confined in a moist environment. Therefore the following procedures will be implemented during construction and operation of the landfill to mitigate the potential for exothermic reactions that could cause a fire.

Control of Organic Material:

- No organic soils will be allowed to be in contact with any of the inert debris or tire bales used in the landfill.
- No organic materials other than dry wood construction debris will be allowed in the landfill.
- Only clean tire bales (no organic debris attached) will be used for construction of berms or subgrade structural fill.

Control of Moisture:

- Only dry or damp debris will be allowed to be buried in the landfill. If wet debris are brought to the landfill, they'll be dried prior to being buried in the cell.
- Up gradient run off will be controlled by interception ditches to prevent any storm water runoff from entering the active cells.

Regular Inspections:

- Each day of operation in the landfill the cells will be inspected for evidence of heat or steam rising out of the cells which may be an indication of an exothermic reaction occurring. If an exothermic reaction is suspected the area will be opened and exposed to the air to be dried out.

Limitation to Sub-Cell (lifts) Depths:

- The depth of each sub-cell (or lift) is limited to 15 feet to allow access to the bottom of the lift with commonly available excavation equipment. Due to the long period of time between cell lift completions (anticipate ~1 year each) all areas of the active cell will be accessible for relatively long period of time for regular monitoring.

Corrective Action Plan

As previously mentioned, the shredded residual material will be sorted through at Central Recycling Services before the inert material is brought to the monofill site. Therefore, it will not likely be necessary to clean up any prohibited or unauthorized waste since there will not be the possibility of hazardous or unauthorized waste being inadvertently brought to the monofill.

The Facility at CRS abides by all regulations and permit conditions regarding inert debris handling, placement and sorting of material, therefore no violations of waste disposal or improper processing will take place at the monofill.

However, if somehow some unauthorized hazardous waste is brought to the landfill that waste will be segregated, reported, and handled like an orphan hazardous waste that shows up on any property. ADEC will be notified and HAZWOPER trained crews will be dispatched to properly control and contain the waste.

Should the unlikely event of a fire occur within the inert waste, there will be fire barriers throughout the monofill. These fire barriers will consist of 12 inch thick soil barriers to act as fire retardants and prevent the fire from spreading from Cell to Cell through the entire monofill. There will also be one foot thick soil barriers between the tire bales retaining structures in each Cell to reduce the possibilities of any fire hazards. For small fires the initial attempts will be to quickly extinguish the fire, using on-site fire extinguishers, before the fire spreads into the waste materials.

If the source of the fire is from an exothermic reaction, then the following actions will occur to control the fire:

- The location of the exothermic reaction will be identified.
- A site specific fire fighting plan will be immediately developed to address the situation which may include the following options:
    - The impacted materials may be dug up and exposed to air to dry out.
    - The cell with the exothermic reaction may be flooded with water to reduce the reaction rate. (use on-site industrial well)
    - Depending on where the fire is located, specific measures will be developed to prevent the spread of the fire to or in the tire bales.

In the unlikely event the fire ignites the tire bales, the local fire department will be notified to monitor and control the fire.

There currently are no structures near the monfill that need to be protected. In the future a scale and scale house will be located near the entrance to the site. The scale and scale house will be located approximately 150' to 200' away from the toe of the monofill. A warm storage building may be added in the future as shown on Sheet 2. Types of equipment that may be onsite: Excavator, Loader, Compactor, Dozer, End Dumps, Truck and Trailer. There is to be a designated fueling area for all equipment to be maintained and fueled on an as-needed basis. This will be located within the Storage area shown on Sheet 2. This area shall also serve as parking for employee vehicles, parking and staging areas for equipment, and staging/storage area for materials. All material will be properly protected and stored.

Waste Placement Plan

The inert material will be placed to fill the natural and manmade voids of this property and take advantage of all the onsite features like existing material berms and valleys.

Before material is placed in the monofill, the bottom layer of the cells will be established using groundwater information. The bottom of the cell will located a minimum of 10' above the established groundwater levels.

In order to recycle tires, build embankments and prevent unstable slopes, tire bales will be used for the purpose of containing inert debris within the limits of the Monofill on the south ½ of the site. They may also be used as structural berms on the North, East and West sides of the fill. Much of the Southeast and Southwest sides of the fill will be located next to natural berms and will require no structural support. CRS will maintain a six inch to one foot of soil separation between each Cell's tire bales to create multiple fire barriers throughout the monofill in the unlikely case of a fire.

Please Refer to Sheet 5, Operations plan for a visual guide to the description below: Cell A will be the first cell to be filled. As per detail 2 on sheet 5, the bottom of the monofill will be established 10 feet above the measured groundwater table. The cell will be built vertically and natural material from the north edge of Cell A and all of Cell J will be used as lift separation material. Cells A and F will be constructed first along with establishment of Cell C as the ACM cell. As Cells A and F progress to a median target elevation (approximately 105' local), Cells G and B will begin to be constructed. The same process will occur to Cells D and H, and then E and I. Once the target elevation is established, construction will move back to Cells A and J and the previous described process will begin again until another lift is completed.

During the above process the following general practices shall apply: The roadway/working area will be wide enough to allow at least two vehicles to pass by one another. The trucks will drive to the end of the operating Cell, turn around, and backup into the most accessible area, then dump its material. As the trucks dump each load of material,

the heavy equipment will then organize and compact the placed debris within the operating Cell.

After each Cell lift is filled completely, a bulldozer will spread 6-12" of excess soil, strippings and non-organic overburden on top of the Cell's inert debris creating a fire barrier. This material will also be spread over and in between the tire bale wall of the Cells to help create a visibly pleasing surface as well as promote the revegetation and growth of native plants.

As sections of the monofill become completed, 24 inches of native or imported soil will be spread over the top to serve as a cap and to allow the reestablishment of vegetation on the site within a reasonable period of time. If the soil cannot support plant growth, 4 inches of topsoil will be imported to promote healthy growth and revegetation of slopes. See Sheet 3 of the plans for slope grades and locations. The slopes will be 2:1 at their steepest when reinforced with tire bales, and 3:1 or less everywhere else. The monofill will all be stabilized to a condition that will allow sufficient moisture to be retained for natural revegetation to occur on site within the next five years.

The placement of inert material is proposed to be a continuous process over the period of approximately twenty five years.

Asbestos Waste Placement Plan (RACM)

Regulated Asbestos Containing Material (RACM) waste will be accepted at the monofill site. All waste that includes regulated asbestos-containing material (RACM) waste will be managed in a manner that prevents the release of asbestos fibers to the air or to surface water and must be disposed of in an approved cell (such as Cell E). The base of the asbestos will be undisturbed earth or stable fill. The cell is located in a manner that it will not preclude any future closeout or remedial action at the facility.

The CRS operator shall inspect each load of RACM waste to assure that the friable asbestos material is sealed in leak-proof bags or containers, labeled in accordance with 29 CFR 1910.1001(j)(4), revised as of July 1, 1998. The waste will be accompanied by a complete and accurate shipment record meeting the requirements of 18 AAC 60.

At the end of each operating day, or at least once every 24 hours while disposal of RACM waste is occurring, the operator shall cover RACM waste that has been deposited at the landfill during the operating day or previous 24 hours with at least six inches of non-RACM material.

CRS will retain a copy of all records required under 18 AAC 60.450 for at least two years, and shall furnish them to the department upon request.

CRS will maintain in the operating record of the landfill a map or diagram showing the boundaries of the asbestos waste management area, its depth, and the amount, in cubic yards, of the RACM waste located there. These will documents will be maintained until the landfill closure is complete.

If excavation of the RACM material is needed for any reason, CRS will submit a work plan prepared in accordance with 18 AAC 60 for approval at least 45 days before excavating or otherwise disturbing any asbestos-containing waste material that has been deposited at the landfill and covered. Department approval of the work plan is required before excavation may begin. If the excavation will begin on a date other than the one contained in the approved work plan, notice of the new date must be provided to the department at least 10 working days before excavation begins. Excavation may not begin earlier than the date specified in the approved work plan.

Non-RACM Waste Placement Plan

Non-Regulated Asbestos Containing Material (Non-RACM) waste will also be accepted at the monofill site.

The majority of the Cells within the monofill will be filled with non-hazardous, inert debris; but when the disposal of Non-RACM is needed, a sub-Cell will be created. When a load of Non-RACM is brought to the monofill, the following process will occur.

The monofill Operator will prepare the operating Cell for the Non-RACM load. The Operator will make a separate Cell within the operating Cell, creating a sub-Cell. Each sub-Cell will be surveyed and the location documented for future reference. To ensure the non-RACM will not become friable during the handling or placement, the sub-Cell will be properly covered, as required for Non-RACM disposal, within the first 24 hours of placement in the monofill with one foot of the CRS Daily Cover. If and when necessary, additional cover will be applied to the Non-RACM sub-Cells to provide the minimum of one foot of cover at all times.

Litter, Vector and Nuisance Control Plan

Throughout each Cell, the equipment will spread Daily Cover, when necessary, to ensure the monofill is properly maintained. This Daily Cover is called Alternative Daily Cover, consisting of material (other than earthen material) that is placed on the surface of the operating Cell of the monofill when needed, to control the unlikely event of fires, odors, blowing litter and scavenging. This Daily Cover will be brought from Central Recycling Services.

Due to the debris being inert, there is no concern for wildlife or domestic animals to be attracted to the inert debris landfill and its operations. Neither odors and/or diseases will be issues on or off site as none of the debris will be putrescible.

CRS plans on preventing any problems or issues that may occur on adjacent properties by using berms, grading plans, dust control and Storm Water Pollution Prevention (SWPPP) techniques throughout the disturbed areas on site. Existing Earth Berms on the South and West sides of the property will not only decrease the visual difference of the property, but to act as a buffer and prevent any material from leaving the site and travel onto any neighboring properties. The North and East sides of the monofill have ~1000' between the toe and a neighboring property. If any issues with blowing debris occur, CMS will implement a plan to combat this including earthen berms and chain link fence.

CRS will provide grading plans and implement the SWPPP for all ground disturbing activities. By applying these SWPPP techniques with the grading plans, this will lessen the amount of water movement on site and will ensure the very limited water discharge off of this property meets water quality criteria. The project is designed to have all water infiltrate the permeable gravel soils or drain into the drainage basin composed of industrial water. Should dust become an issue on site, CRS has access to available water trucks when needed.

The existing surrounding land uses within one mile around or adjacent to Lot C10 include: single family residential homes to the West, industrial mining operations to the Northeast, and Southeast and privately owned farming/agricultural due east. This property has been used for gravel mining operations in the past so CMS's future purpose for these properties and these plans will not interfere with the neighboring lands' uses or activities.

The initial projected average daily truck count is about 12, with truck counts of up to 25 per day for short periods of time. Gravel extraction haul trucks use the existing driveway located on Lot C10 and have historically had much larger volumes of trucks on a daily basis. CMS has Grandfather Rights to the driveway and gravel permit. It is not anticipated that a noticeable increase will occur in the noise or the truck traffic on the Glenn Highway.

Monitoring Plan

Due to the inert material being placed in this landfill and the drainage plan, no surface water or ground water is expected to be impacted. Visual inspections will occur on a regular basis following the attached inspection checklist. While limited daily inspections will be conducted whenever the landfill is in operation, at a minimum monthly inspections will be conducted following the entire checklist by a person familiar with all the permit requirements.

***Permit:** Alaska DEC, Solid Waste Program*
***Applicant:** Central Monofill Services, Inc.*

Acceptable Waste Policy

Acceptable Waste

Acceptable:	Household refuse Commercial refuse Asbestos (with prior notice and approval - call 861-7601 or 861-7604) Refrigerators All items brought in for disposal must be 8 feet in length or less. Any item longer w have to be cut down prior to bringing it to the Landfill or any of the Transfer Sites.
Recycle Material:	Used oil Lead acid batteries Aluminum * Nonferrous metals (copper, brass, etc.) * Electronic Equipment (computers, monitors, TV's) - Are accepted on Wednesday and Saturday (fees apply).

* Separate recycle material and deposit in bins as directed by the Gate House Attendant

Waste that is Not Acceptable

Not Acceptable:	Burning or smoldering material Explosives ** Radioactive material Junk vehicles Narcotics, prescription drugs Sewage, sludge, human excrement, except disposable diapers Tree stumps Tree or brush cuttings exceeding one (1) pick-up load Hazardous waste as defined by the U.S. Environmental Protection Agency (EPA)

** These materials are not accepted at any of the facilities. Contact the Alaska State Troopers for disposal assistance at (907) 745-2131.

The Matanuska-Susitna Borough also has an area for construction and demolition materials at Central Landfill. This consists of materials such as wood, sheetrock, glass, tires, concrete, and other inert materials of this nature. These items may be disposed of at a reduced per ton rate.

Residents may also wish to come into the construction/demolition area to salvage useful materials. A waiver must be signed prior to salvaging in this area. More information is available about salvaging at the Central Landfill Scale House.

Re: Central Monofill Services

Ms. Lee –

Central Monofill Services' umbrella policy provides excess limits over their primary polices: General Liability including Pollution Liability / Professional Liability, Business Automobile, and Employers Liability policies. Please see the table below which explains how the limits apply to each policy.

Coverage	Primary Limits	Excess Limits	Total Limits
General Liability, including Pollution	$1,000,000 (per occurrence)	$9,000,000	$10,000,000
Professional Liability	$1,000,000	$9,000,000	$10,000,000
Business Automobile	$1,000,000	$9,000,000	$10,000,000
Employers Liability	$1,000,000	$9,000,000	$10,000,000

If you have any questions, please do not hesitate to contact me.

Thank you

Regards,

Attn: Larry A. Helgeson, P.E.

RE: STABILITY ANALYSIS FOR THE PROPOSED TIRE BALES REINFORCED LANDFILL SLOPE, CHUGIAK, ALASKA

Larry,

Per your request, Northern Geotechnical Engineering, Inc. *d.b.a.* Terra Firma Testing has prepared this letter as an addendum to our previous geotechnical report, "Stability Analysis for the Proposed Cut Slope, Chugiak, Alaska", dated December 19, 2013. As mentioned in previous letter, proposed developments of the property include cutting the top portion of the existing slope, and constructing a landfill slope near the toe (Figures 1, 2 &3). This letter presents the results of our analysis of the proposed tire bales reinforced landfill slope.

The design calls for a landfill slope inclined at 2H:1V with an approximately vertical height of 70 feet. For the analysis, we included analysis results of slopes inclined 1.2H:1V, 1.5H:1V and 2H:1V. A 20 feet thick tire bales wall was laid out on the proposed landfill slope as reinforcement. The tire bales properties were adopted from "Engineering Properties of Tire Bales for Soil Repairs and Embankment Construction" (Zornberg and LaRocque, 2005), provided by client. Material properties for modeling are shown in Figures 4-9.

Geo-fabric Reinforcement

Preliminary analyses concluded that the tire bales wall would not meet the MOA and code requirements for stability at economically steep configurations. For this project, the MOA requirement of a static factor of 1.7 and a seismic factor of safety of 1.1 was used. To increase the factor of safety, a tieback system was introduced into the model. Especially with the compressible, low-weight backfill, a geo-fabric tie back system appeared to be

most appropriate considering that the geo fabric would serve dual functions by reinforcing the wall and to minimize differential settlements in the backfill near the tire bales wall.

With geo-fabric reinforcement, the bond length is assumed to be equal to the fabric length. The width of the fabric (distance into the section) is always at unit thickness (1 meter or 1 feet), matching the unit thickness of the slope model. It is assumed that the stabilizing resisting force from the fabric acts in the axial direction parallel to the fabric.

Within the model, four layers of geo-fabric were set up at every 15 ft. intervals. The tensile capacity of each layer was varied until the minimum required factors of safety for the overall slope stability were achieved. Also included in the analysis is factor of safety for the tensile strength of the geo-fabric (1.5). The applied loads represent the ultimate capacity of the fabric.

Table 1: Geo-fabric Applied Load for 1.2H:1V Landfill Slope

Analysis Results

Six runs were conducted to assess the proposed tire bales/geo-fabric reinforced slope stability for the simplified cross section as shown in Figure 3. Each run selected failure surfaces and found a minimum factor of safety. The results of the analyses for the proposed tire bales/geo-fabric reinforced landfill slope are summarized as follows:

- For the representative parameters shown in Table 1, the proposed 1.2H:1V landfill slope reinforced by 20 feet thick tire bales wall at the cross section location appears to be stable under static condition with a minimum factor of safety 1.9 (Figure 4); while it appears stable under a pseudo-static seismic load of 0.3g, having a minimum factor of safety of 1.1 (Figure 5).

- For the representative parameters shown in Table 2, the proposed 1.5H:1V landfill slope reinforced by 20 feet thick tire bales wall at the cross section location appears to be stable under static condition with a minimum factor of safety 1.8 (Figure 6); while it appears stable under a pseudo-static seismic load of 0.3g, having a minimum factor of safety of 1.1 (Figure 7).

- For the representative parameters shown in Table 3, the proposed 2H:1V landfill slope reinforced by 20 feet thick tire bales wall at the cross section location appears to be stable under static condition with a minimum factor of safety 2.4 (Figure 8); while it appears stable under a pseudo-static seismic load of 0.3g, having a minimum factor of safety of 1.1 (Figure 9).

Conclusion and Closure

This preliminary analysis shows that is possible to construct a fill of recycled, shredded construction debris using tire bales to develop the slope face. Further analyses can be conducted to optimize the fabric spacing, fabric type, slope face angle, and construction methodology with the cost of materials and construction. Because the construction of the fill is expected to take many years, the cost optimization may not remain a constant. It is entirely possible to alter the slope face angle, fabric type and strength, and fabric spacing during the life of the project to meet current cost optimization.

Northern Geotechnical Engineering Inc. prepared this letter exclusively for the use of the *Environmental Management, Inc.* and their contractors for use in design and construction

of the proposed development. *Northern Geotechnical Engineering, Inc. d.b.a Terra Firma Testing* should be notified if significant changes are to occur in the nature, design, or location of the proposed facilities in order that the conclusions and recommendations presented in this report may be reviewed and, if necessary, modified to satisfy the proposed changes.

Northern Geotechnical Engineering, Inc. d.b.a Terra Firma Testing conducted this evaluation following the standard of care expected of professionals undertaking similar work in the State of Alaska under similar conditions. No warranty expressed or implied is made.

We appreciate the opportunity to provide you with our services. If you have any questions, please do not hesitate to contact us at your convenience.

Sincerely,
Northern Geotechnical Engineering, Inc. *d.b.a.* Terra Firma Testing,

Permit: *Application for a Conditional Use Permit- MSB 17.60*
Applicant: *Central Monofill Services*
Date Submitted: *January 15, 2014*

for these complaints has not been corroborated and may be the result of other variables including normal variations in seasonal weather events. CMS is working cooperatively with the State of Alaska Department of Natural Resources to monitor the water levels in these ponds to accurately determine what if any impact occurs to neighboring lakes. CMS CUP application maintains a setback from the ponds for both the storage of materials and monofill materials. Proposed activities related to the recycle facility and monofill will not require any alterations to the ponds or aquifer. The ponds are not included in the area requested for CUP.

Maddox & Associates was hired to perform an independent review of the site hydrology and leachate concerns raised with the proposed CMS Monofill. Maddox & Associates is a nationally recognized professional hydrogeologist with experience evaluating contaminate potential in over 50 sanitary landfills in the US and Canada. Mr. Maddox looked at everything from rainwater infiltration through the monofill, potential leachate, ground water movement and potential worst case scenarios. The Maddox report and associated findings are attached. In summary Mr. Maddox found that *"the construction and operation of the proposed monofill will not present a threat to groundwater beneath the site, nor down-gradient of the site."*

A previous report by the National Demolition Association, entitled "Demolition Contractors Manage and Dispose of Waste Responsibly" confirms Mr. Maddox's findings. This report is attached and in summary finds, "For years, these facilities have accepted construction/demolition wastes and, when managed properly, pose no significant threat to the environment." "These findings support National Demolition Association's conclusion that properly designed, well maintained and operated demolition waste landfills are the most economical and environmentally sound method to manage that portion of the demolition industry's waste which cannot economically be recycled." The proposed CMS Monofill will be the first in Alaska to meet the National Demolition Association guideline for prudent, environmentally responsible operations.

To further insure the protection of the Groundwater CMS has installed monitoring wells around the site. Water level data is being shared with Alaska Department of Natural Resources for regional study of ground water table elevations.

The site has been previously completely stripped of trees reducing any potential animal habitat issues. C&D material is considered inert and non-putrescent, so it does not attract animals or birds. The CRS facility in Anchorage has processed C&D materials since 2009 with no animal attraction issues to any of the materials handled or processed.

Subject: Matanuska-Susitna Borough Central Landfill
Solid Waste Permit No. SW1A007-15

Dear Ms. O'Neil:

The Alaska Department of Environmental Conservation (ADEC) has completed its evaluation of your permit application for the Matanuska-Susitna Borough (MSB) Central Landfill, dated November 3, 2010. Please review the conditions and stipulations in the permit and ensure that they are understood. This permit is being issued in accordance with Alaska Statute (AS) 46.03; Title 18, Chapter 15 of the Alaska Administrative Code (18 AAC 15); and the Solid Waste Regulations (18 AAC 60).

Any person who disagrees with this decision may request an adjudicatory hearing in accordance with 18 AAC 15.195 - 18 AAC 15.340 or an informal review by the Division Director in accordance with 18 AAC 15.185. **Informal review requests** must be delivered to the Division Director, Alaska Department of Environmental Conservation, 555 Cordova Street, Anchorage, AK 99501 within 15 days of the permit decision. **Adjudicatory hearing requests** must be delivered to the Commissioner of the Department of Environmental Conservation, 410 Willoughby Avenue, Suite 303, Juneau, Alaska 99801, within 30 days of the permit decision. If a hearing is not requested within 30 days, the right to appeal is waived. More information regarding submitting a request for an informal review or adjudicatory hearing may be found at www.dec.state.ak.us/commish/ReviewGuidance.htm. Even if an adjudicatory hearing has been requested and granted, all permit conditions remain in effect unless a stay has been granted.

If you have any questions, or require any additional information, please contact Doug Huntman at (907) 269-7642 or by email at doug.huntman@alaska.gov

Sincerely,

Lori Aldrich
Solid Waste Program Coordinator

Attachment: Permit # SW1A007-15, expiring on **November 19, 2015**
cc: Greg Goodale, MSB

STATE OF ALASKA
DEPARTMENT OF ENVIRONMENTAL CONSERVATION
555 Cordova Street
Anchorage, AK 99501

SOLID WASTE DISPOSAL PERMIT

Permit No. **SW1A007-15**

Date Issued: November 19, 2010
Date Expires: November 19, 2015

The Alaska Department of Environmental Conservation (ADEC), under authority of AS 46.03 and 18 AAC 60, issues a solid waste disposal permit to:

Matanuska-Susitna Borough
Palmer Central Landfill
350 E. Dahlia Avenue
Palmer, AK 99645-6488

and designated representatives for the management and operation of a Class I municipal solid waste landfill. It authorizes operation of municipal waste cells 2A, 2B, cell 3, and separate cells for construction and demolition (C&D) waste and asbestos containing material.

The landfill is located at Milepost 3 of the Palmer-Wasilla Highway at the southern end of North 49th State Street. The active landfill is currently limited to an approximately 160-acre section of the 620-acre site, legally described as S ½ Section 1, E ½ SE ¼ Section 2, NE ¼ NE ¼, E ½ NW ¼ NE ¼ Section 11, N ½ NW ¼, N ½ SW ¼ NW ¼, N ½ SE ¼ NW ¼, NW ¼ NE ¼ of Section 12, Township 17 North, Range 1 East, Seward Meridian.

The permit holder shall manage and operate the facility in accordance with:

- 18 AAC 60
- permit application materials submitted November 3, 2010, and additional application materials submitted November 19, 2010

In addition, the following permit conditions are required:

Specific Conditions

Explosive Gas Monitoring Plan

1. MSB must submit a facility wide gas monitoring plan, including installation of a gas monitoring well system that meets the requirements of 18 AAC 60.350. The plan must be submitted to ADEC for approval, no later than June 1, 2010 and the gas monitoring wells must be installed and operational no later than June 1, 2012.

Landfill Closure

1. MSB must submit a facility wide conceptual closure plan that meets the requirements of 18 AAC 60.395, no later than June 1, 2011. The closure plan should include intended closure sequence for all landfill cells you expect to operate over the life of the landfill. The plan must also include updated calculations of the cost estimate for closure and post-closure care of the landfill.

Facility Design

1. Limit vertical expansion of the landfill cells to 340 feet elevation.

Facility Operations

1. For noise control:

   a. Not operate any heavy equipment or commercial size trucks at the landfill working face from 9 p.m. to 7 a.m., excluding emergency situations;
   b. Only operate vehicles at the landfill with properly sized and functional mufflers installed;
   c. Not operate construction equipment or commercial size trucks at the landfill from 10 p.m. to 6 a.m. for the construction of new landfill cells.

2. Maintain a minimum separation distance of 50 feet between the active placement of solid waste and the facility boundary, except next to residential areas. All new cells next to residential areas must have a separation distance of 300 feet between the cell boundary and the facility boundary.

3. Ensure that landfill personnel conduct random waste inspections of incoming loads on a weekly basis to check for prohibited wastes. Ensure that landfill personnel receive adequate training in the identification of hazardous waste and prohibited waste. Maintain a record of the random inspections noting the date, inspector name, and any prohibited wastes identified. The inspection records shall be maintained in the facility record.

Municipal Waste Cell Operations

1. Ensure that only one working face/dumping location for municipal waste is exposed at any one time, and that it is located within the footprint of cells 2A, 2B or cell 3. The maximum size of the working face shall not exceed 200 feet wide and 10 feet tall.

2. Maintain a slope no greater than 3 to 1 (horizontal to vertical) on interior slopes of the cells. Interior slopes are those that will have waste placed against them at some time in the future based on the approved facility plans.

3. Maintain a slope no greater than 4 to 1 (horizontal to vertical) on all exterior slopes of the cells. Exterior slopes are those that will not have waste placed against them in the future based on the approved facility plans.

Construction & Demolition (C&D) Cell Operations

1. Ensure that only one working face/dumping location for C&D waste is exposed at any one time.

2. Compact, consolidate, and cover the C&D waste monthly or more frequently if needed to control litter and vectors.

3. Ensure that no asbestos containing material (ACM) is disposed in the C&D cell.

Asbestos Cell Operations

1. Ensure that all ACM is disposed in the asbestos cell. Friable ACM must be sealed in leak-proof bags or containers with proper labeling prior to acceptance at the facility. Non-friable ACM, if not containerized, must be deposited in the designated asbestos disposal area in a manner that does not result in breakage and the subsequent release of asbestos dust.

2. Ensure that all asbestos-containing waste material is covered with at least six (6) inches of soil material by the end of the day of disposal.

3. Ensure that a designated representative is present at the site to supervise each disposal.

Visual Monitoring

1. Visually monitor the site each month for signs of damage or potential damage from settlement, ponding, erosion, leachate seeps, animal attraction and compliance with other permit conditions. Record the inspection results on the form submitted in the monitoring plan. Maintain the inspection results in the facility's operating record.

Groundwater Monitoring

1. Conduct groundwater monitoring at the facility as described in the monitoring plan, dated October 2010

    a. Groundwater elevations for all wells must be recorded at each sampling event.

    b. For wells designated for detection monitoring, test all water quality samples for the constituents listed in Appendix I of Title 40, part 258 of the Code of Federal Regulations (40 CFR 258) and the following compounds from Table J of 18 AAC 60: specific conductivity, temperature, pH, Chloride, DRO, GRO, Mercury, and Total Dissolved Solids.

    c. For wells subject to assessment monitoring, test all water samples for all constituents listed in Appendix II of 40 CFR 258 in the June sampling. In the December sampling, these wells must be tested for Appendix I constituents, plus any Appendix II constituents detected above the method detection limit (MDL) at the facility in any sampling event.

d. No later than 60 days after receiving the laboratory results for a monitoring event, submit a report to ADEC in an approved format including the appropriate analyses.

General Conditions

1. Access and inspection - The Permittee shall allow the Commissioner or his representative access to the permitted facilities at reasonable times to conduct scheduled or unscheduled inspections or tests to determine compliance with this permit, State laws, and regulations.

2. Information access - Except for information relating to confidential processes or methods of manufacture, all records and reports submitted in accordance with the terms of this permit shall be available for public inspection at the State of Alaska, Department of Environmental Conservation, 555 Cordova Street, Anchorage, AK 99501.

3. Civil and criminal liability - Nothing in this permit shall relieve the Permittee from civil or criminal penalties for noncompliance, whether or not such noncompliance is due to factors beyond his control, including, but not limited to, accidents, equipment breakdowns, or labor disputes.

4. Availability - The Permittee shall post or maintain a copy of this permit available to the public at the disposal facility.

5. Adverse impact - The Permittee shall take all necessary means to minimize any adverse impacts to the receiving waters or lands resulting from noncompliance with any limitation specified in this permit, including any additional monitoring needed to determine the nature and impact of the non-complying activity. The Permittee shall clean up and restore all areas adversely impacted by the noncompliance.

6. Cultural or paleontological resources - Should cultural or paleontological resources be discovered as a result of this activity, work which would disturb such resources is to be stopped, and the State Historic Preservation Office, Division of Parks and Outdoor Recreation, Department of Natural Resources, is to be notified immediately (907-269-8721).

7. Applications for renewal - In accordance with 18 AAC 15.100(d), applications for renewal or amendment of this permit must be made no later than 30 days before the expiration date of the permit or the planned effective date of the amendment.

8. Other legal obligations - The requirements, duties, and obligations set forth in this permit are in addition to any requirements, duties, or obligations contained in any permit that the Alaska Department of Environmental Conservation or the U.S. Environmental Protection Agency has issued or may issue to the Permittee. This permit does not relieve the Permittee from the duty to obtain any and all necessary permits and to comply with the requirements contained in any such permit or with applicable state and federal laws and regulations. All activities conducted by the Permittee pursuant to the terms of this permit

and all plans implemented by the Permittee pursuant to the terms of this permit shall comply with all applicable state and federal laws and regulations.

9. Pollution prevention - In order to prevent and minimize present and future pollution, when making management decisions that affect waste generation, the Permittee shall consider the following order of priority options: waste source reduction; recycling of waste; waste treatment; and waste disposal.

This permit expires on November 19, 2015 and may be revoked or amended in accordance with 18 AAC 60.260. The permit can be renewed if the facility will operate beyond this date. **To avoid expiration of this permit, a renewal application must be submitted to ADEC at least 30 days before the expiration date, as set forth in 18 AAC 15.110.**

MEMORANDUM

DATE: October 7, 2011

FROM: Susan Lee, Planner II

SUBJECT: REQUEST FOR REVIEW AND COMMENTS

PROJECT: **Conditional Use Permit for a Salvage Yard**

PARCEL ID: 16N03W24D009 & 4617000L002B **TAX MAP:** GB 08

LOCATION: Township 16 North, Range 3 West, Section 24, Seward Meridian

APPLICANT: Tri-Metal International LLC

A conditional use permit application has been submitted for the operation of a salvage yard for the collection, cutting, and staging of material for export from Port MacKenzie. The Planning Commission will conduct a public hearing on this request on November 21, 2011. If we do not receive comments from you we will assume you have no objections to the proposed project.

BASIC APPLICATION FOR CONDITIONAL LAND USE PERMIT

Application Fee is $500 for proposed development and $1500 for "After the Fact" development. The application fee, must accompany this application. Prior to the application's presentation to the Planning Commission, applicants must also pay cost of required mailings and advertising. Applicants will be provided notice of charges due. Discuss the application process with MSB Planning Department staff before completing the application. Submit the application to the MSB Code Compliance Division at the address listed above.

Most of the application will be additional information provided by the applicant. Incomplete applications will not be processed. Carefully read the appropriate MSB codes, questionnaires and instructions. Fill out forms completely. Check the appropriate □. Use N/A if a question is not applicable. Attach additional pages as needed. For more information go to www.matsugov.us , and click on code compliance.

Is this application for a; □ proposed (new) □ use □ structure,
a "After the Fact" (existing) □ use □ structure,
□ Change or expansion of an existing conditional use permit (CUP) □ use □ structure,
□ Preexisting Legal Nonconforming (Grandfather Rights) □ use □ structure,
The proposed development is; SCRAP METAL STAGING BUILDING
The proposed development requires a conditional use permit under MSB 17.60.030
At a minimum, this application must provide sufficient information to meet area wide borough codes and,
Specific application requirements of MSB Code 17.60.100 and, General
CUP standards of MSB Codes _____ and,
Special CUP standards of MSB Code _____
Special CUP questionnaire(s) are attached _____ □ Yes □No □ N/A
PROJECT LOCATION: Township: 16N, Range: 03W, Section: 24, Meridian SEWARD
SUBDIVISION: _____ BLOCK: _____, LOT: D-2-9
(US Survey, aliquot Part, Lat. /Long. etc) _____
STREET ADDRESS: 10405 S. KNIK-GOOSEBAY ROAD
VICINITY: _____
LOT SIZE: Acres 34.04 *or* _____ Square Feet
Is site in a Special Use District (SPUD) or city? Yes, Name KNIK SUBDIST 1 RECREATION No,
Development and use must also comply with the rules for the SPUD and city.

Ownership: *If the applicant is not the owner of record, a letter of authorization signed by the owner must be attached to this application.* Is authorization attached? □ Yes □No □ N/A

For MSB Staff use: MSB TAX PARCEL ID _____ ***MSB FILE CUP #*** _____

This Application is for; ☐ **New Use,** ☐ **New Structure,** ☐ **Modification of Existing Use,** ☐ **Modification of Existing Structure**

Type of Use(s): ☐ Commercial, ☐ Industrial, ☐ Home Occupation, ☐ Home Based Business, ☐ Retail, ☐ Wholesale, ☐ Office, ☐ Auditorium/Restaurant, ☐ Manufacturing, ☐ Processing/ Repairing, ☐ Warehousing/ Storage ☒ Salvage yard, ☐ Adult Oriented Business, ☐ Alcohol Beverage (Bar and Lounge), ☐ Alcohol Beverage (Package liquor sales) ☐ Mobile Home Park, ☐ Mobile Home Placement, ☐ Racetrack, ☐ Community Correctional Residential Center,
☐ Natural Resource Extraction, Total cubic yards _____, Cubic yards per year _____
☐ Residential; Number of dwelling units _____, ☐ Other _____
Describe Project: TRELAND IS BEING USED TO RE-SIZE SCRAP STEEL FOR EXPORT FROM PORT MACKENZIE.

Is this an Expansion of Preexisting Legal Nonconforming Use or Structure? ☐ Yes ☒ No
If yes, this use has lawfully existed in this location since what date? ☐ Yes ☐ No ☒ N/A
If yes, has the nonconforming use, been discontinued for more than twelve consecutive months since it began? ☐ Yes ☐ No ☒ N/A
If yes, list the date the use was discontinued _____ **and date use resumed** _____
To establish Grand Father Rights for a use, complete this form (including attachments) also include a copy of the earliest Business Licenses and other evidence of the continued existence of the use at this site since the date the use became nonconforming. **Is evidence attached?** ☐ Yes ☐ No ☒ N/A
Grand Father Rights for structures are processed under MSB 17.80.
Describe the proposed expansion/increase of the Preexisting Legal Nonconforming Use:

Plans and Drawings: (Note some codes require surveys and drawings prepared by certified professionals)
Plans and drawings must provide all information required by the code regulating the subject development. Attach a detailed Site Plan and dimensional drawings of the horizontal views of structures (drawn to scale) showing, at a minimum, the location of setbacks, easements, all existing and proposed buildings and structures, (including tanks and chemical processing equipment), access points, buffering, vehicular and pedestrian circulation patterns, parking, loading, storage and processing areas, lighting, topography, drainage management plan, sources of noise, water bodies, visual and sound buffers, fences, berms, landscaping, adjacent: streets, public easements and rights of way.

Structural drawings should depict height, width volume, appearance, modifications, identify use areas with locations and dimensions, delineate areas of expansion or change in use, and other details sufficient to adjudicate the application.
Are Site Plans and structural drawings attached? ☒ Yes ☐ No

Structure(s): *If more than one structure is proposed, attach requested information about each.*
☐ None, ☐ Existing, ☒ Proposed New Structure(s) how many new structures 1, ☐ Relocation,
☐ Addition, ☐ Alteration/Remodel, ☐ Repair/Replacement, ☐ Basement/Daylight Basement,
☐ Tower(s); Type: _____
Number of Stories above avg. grade: _____, Maximum Height of Structure above avg. grade: _____
Total Exterior Gross sq. ft. of Building: _____ ☐ Ditches,
☐ Parking Lot Area _____, ☐ Storage Yard Area _____, ☐ Ponds Area _____
☐ Fill Cubic Yards: _____, ☐ Excavation Cubic Yards: _____

Structural Setbacks: *Measure from closest point of structure(s) to:*
Right of Way and Public Use/Access easements _____ ft *(Minimum 25 ft.)*,
Side Lot Line _____ ft *(Minimum 10 ft.)*, Rear Lot Line _____ ft *(Minimum 10 ft.)*, Waterbody _____ ft
(Minimum 75 ft. for habitable structures and garages)

Water Frontage: Does the property have water frontage? ☒ Yes ☐ No ☐ N/A
Name of Water Body: KNIK ARM

Access /Driveway: This project will access what street (s)? KNIK-GOOSE BAY ROAD
Is the street: ☐ Borough Maintained, ☒ State (ADOT/PF) Maintained, or ☐ Private?
Will this project require a new, or modified, driveway to a street or road? ☐ Yes ☒ No ☐ N/A
Does this project have an existing Driveway permit? ☒ Yes ☐ No ☐ N/A
Driveway permit may be required, call 745-4801 (MSB Public Works Dept); or 745-2159 (AK DOT-PF)

Water Supply: ☐ None ☐ Existing ☐ Proposed ☒ Private well/cistern ☐ Public/Community
ADEC Certification may be required, contact Alaska DEC at 376-1850 (www.state.ak.us/dec) ADNR Water Rights may be required, contact Alaska DNR at 907-269-8503(www.dnr.state.ak.us).

Sewage Disposal: ☐ None ☐ Existing ☐ Proposed ☐ Pit Privy ☐ Holding Tank ☐ Septic Tank ☐ Public/Community ☒ Other (specify) PORT-A-POTTY FOR EMPLOYEE USE
No part of a subsurface sewage disposal system shall be closer than 100 ft from any body of water or water course (MSB Title 17.55.020). Other rules apply. ADEC Certification may be required, call Alaska DEC at 376-5038 for more information. Connection to available public systems (such as Talkeetna) may be required. Contact MSB Public Works Dept. at (907) 745-9801.

EXISTING Land Use on Adjacent Lots:
North: 4 HOMES ACROSS HWY FROM PROPERTY APPROXIMATELY 571' FROM SITE
South: KNIK ARM - NO VISIBLE USES
East: KNIK ARM West: 4 HOMES APPROXIMATELY 378' FROM SITE
Other:

OTHER PERMITS, COVENANTS, PLAT NOTES, DEED RESTRICTIONS, ETC
It is the responsibility of the owner and applicant to identify and comply with all applicable private restrictions such as covenants, and plat notes, as well as all local, state and federal regulations applicable to this development and to obtain all necessary authorizations and permits. Any commercial use requires State and Borough Business licenses. City business licenses may also be required. State Fire Marshall's review may be required; call (907)269-5604 for state fire and building codes.

The applicant has determined the following authorizations or permits are required for this project:
Permit name/#_____ _____ Applied for, issued
Permit name/#_____ _____ Applied for, issued
Permit name/#_____ _____ Applied for, issued
Permit name/#_____ _____ Applied for, issued
An Alaska Coastal project questionnaire is helpful in determining if state or federal resource management permits are required. These forms are available from the borough or at the ADNR website, www.alaskacoast.state.ak.us. Coastal Project Questionnaire attached Yes No

Statement
I am the owner, or owner's representative, of the above described property and I hereby apply for a conditional use permit in accordance with the requirements of all applicable MSB ordinances.

I understand that by making application for a conditional use permit, the owner grants permission for borough staff member(s) to enter onto the property for the purpose of processing the application and monitoring compliance with code and permit requirements.

I understand that other rules such as local, state and federal regulations, covenants, plat notes, and deed restrictions may also be applicable and other permits may be required. I understand that it is the responsibility of the owner and operator to identify and comply with all applicable rules.

I further understand that the Borough Planning Commission may impose additional conditions and safeguards designed to protect the public's health, safety, and welfare and to ensure the compatibility of the conditional use with other lawful uses.

The information submitted in this application is accurate and complete to the best of my knowledge.

Tri Metal International LLC Conditional Use Permit

We are applying to acquire a conditional use permit to allow us to collect, cut, and stage material on a private lease site located at 10405 S. Knik-Goosebay Road (hereafter referred to as the site). We are finishing preparations for our first load to ship out between October 10th – 15th. We have already stockpiled approximately 5200 tons of steel at our permit site at Mile 19 Point MacKenzie Road. At our current production we expect to have 6000 tons or more available to load onto the ship. This would be the first actual shipload of steel to be exported from Alaska, and it will be exported from the borough's port. This is an important milestone in the Mat-Su Borough's history.

Our company was organized as a Limited Liability Company in the state of Alaska on October 25, 2009. We have worked in Alaska since then acquiring material to export from Port MacKenzie. We were performing most of the prep work at the site of the acquired material, but found it to be more efficient to bring larger pieces to one central location for re-sizing and removal of non-steel components.

Since June of 2011, we have processed approximately 3000 tons of steel through the site in question. It has been done safely for the public, our personnel, and the environment.

The site is accessed from a driveway off of Knik-Goosebay road at approximately mile 13.9. As the site has been operated as a gravel pit for at least the last 5 years, the driveway is constructed to allow multiple trucks a day both in and out(see photo #1 of the attached photos). The site possesses a natural treed barrier and is not visible from the roadway. With the prior use as a gravel pit, it also sits below the surrounding area. From the driveway, the trucks follow the road down into the pit and around to the scale house (Photo #2) for weigh in. After weigh in, the trucks proceed to where we offload the material (Photo #3).

To unload the trucks, unless they are towing trailers designed for dumping, we have been using either our crane (Photo #4), or one of our excavators (Photo #5) to remove the material from the truck. If the truck is equipped with a dump bed or a trailer capable of dumping the procedure is similar, except they dump their contents. After emptying the load they return to the scale to weigh out. The trucks then follow the road back to exit onto Knik-Goosebay Road.

At this time, we are not accepting material that has contaminants as we are not currently setup to handle large quantities of oil, hydraulic fluid, etc. We do check materials for any potential contaminants and if any are found, they are removed into sealable containers for disposal. Disposal will be by taking the materials to Mat-Su Central Landfill. Next, they are then checked for non-ferrous(anything other than steel) materials that are removed for separate recycling from the steel. Last, they are given to our crews that resize the material into pieces no bigger than 37 inches at the widest point.

Once the material is ready for the cutting crew, they use propane and oxygen torches to size the material. This setup was chosen because of the clean burning aspect of propane, as well as affordability and accessibility. With each person setup on a per ton basis, they each keep a separate completed pile (Photo #6) that is loaded into side dump semi-truck trailers. The trucks facilitating this move follow the same procedure as described previously for trucks coming into the site, just reversed as they scale first empty, are loaded, and then scaled full. The material is then taken to our permit site located at mile 19 Point MacKenzie Road. Once there it is neatly stacked and awaits the ships arrival. That concludes what we are doing currently.

Future plans:

Our lease space as it stands currently is set to expand to the proposed area shown on the site plan. We are planning the construction of up to a 300-foot x 150-foot building to allow us to accept materials which may still contain oil, antifreeze, gasoline, etc. The goal is to drain all liquids for re-use, if possible such as waste oil for heating the building, or proper disposal. The building will serve as storage for all of our tools and equipment when not in use. It is also planned to house our offices and employee break room in the same structure. The exact location, shape, and type of building have yet to be determined, but the rough area of placement has been shown on the site plan.

We are currently in negotiations to place a liquid oxygen generation plant on the site. The plant will be for our company use only with no intention of being a retail sale location. The costs for the installation of the plant are estimated to be $100,000, plus the expense of training select employees on the use of the equipment to fill the oxygen bottles. The location is shown on the site plan for intended plant placement. The reason behind the liquid oxygen generation plant is to minimize transporting liquid oxygen on the road system. Potential injury to the public due to unforeseen circumstances while transporting increases with increased hauling. The only facility to get the quantity of oxygen we are using is the Air Liquide bulk plant in Anchorage.

Depending on space available at the site, one potential expansion would be a large scale shredding facility. We are considering if there might be a site inside the port district, near rail, road, and dock that would offer long-term leasing for this investment. This final site decision will be made at a later date. This facility would have the capacity to shred whole cars and large pieces of steel. It would also be able to sort and separate out different types of materials. This shredder would produce ready to ship materials, with no further processing needed.

We are currently in negotiations with Prudhoe Bay contractors for removal of steel from the area for processing and shipping out from Port Mackenzie. We also are in negotiations for the tear down and removal of a derelict tank farm in Fairbanks, Alaska. This would also pass through this site for processing. We have material in Canada we will be preparing to ship to the site. We are constantly looking for more material, and have contacted BLM to be contacted for removal of abandoned mining equipment and machinery.

Another potential source of steel we are exploring is to work in conjunction with Port MacKenzie in the construction of a dry dock for us to bring large ships for tear down (referred to as ship breaking). The construction of said dry dock would allow us to do this, as well as the potential to allow other ships to dry dock for repairs and maintenance. This is a long-term goal and will not see a decision on this until 2015 or later.

Addendum to Tri Metal International LLC Conditional Use Permit

Per the Borough's request, here is additional information regarding our permit application.

The conditional use permit application we supplied is for a lease that overlaps parcels 16N03W24D009(10405 S. Knik Goose Bay Road) & 4617000L002B (10425 S. Knik Goose Bay Road). Only the first address was listed on the application. We need it to cover both parcels in the lease.

The scale house that was talked about at our meeting and shown on our site plan belong to Stepper's Construction, we have no interests in it other than the use we are allowed. There are no set vehicular or pedestrian patterns to show on the site plan as the roadway is not consistent due to gravel extraction and pedestrian traffic is non-existent on the site. Parking areas are also not shown either due to the changing topography of the site and no defined area will be set aside for this purpose.

The site plan has been updated to label the separate lease lots, the future oxygen plant, acreage of each lease lot, width of the access road, specific uses and drainage of the site.

EXECUTIVE SUMMARY

A groundwater modeling study was performed to assess the impact of dredging at Anchorage Sand and Gravel, Inc.'s (AS&G's) Palmer gravel pit. The proposed dredging operation would create a 130-acre lake approximately 100 feet deep. The purpose of the modeling effort was to provide an objective determination of the approximate lake elevation, and to assess potential impacts on nearby lakes and wells. For transparency to reviewers, the model is intended to be as simple as possible. This was accomplished by using the minimum number of layers needed to represent the groundwater flow system: one layer for aquifer materials that will be removed by dredging, one layer for aquifer materials that will remain after dredging, and one layer for bedrock. Around the perimeter of the model, a constant head boundary is used to mimic the regional water table slope. Local changes in water table slope are reproduced using the bedrock surface mapped using AS&G drill holes and a single zone of reduced hydraulic conductivity exposed as a silt lens on the adjacent property. The model uses a regional hydraulic conductivity value based on two high-capacity pumping tests that agree both internally and with nearby well yields. A reduced hydraulic conductivity for the silt lens is supported by adjacent pond elevations and by a domestic well test where the silt lens extends onto AS&G's property. Based on these data, the model reproduces the July 8, 2010 water table configuration with an average error within 0.5 feet, and within 0.2 feet through most of the model domain.

Although the model reproduces the July 8, 2010 water table configuration remarkably well, the model's parameter values and boundary conditions do not constitute a "unique" solution to the groundwater flow problem. That is, a slightly different set of parameter values and boundary conditions might produce an equally good fit. However, the selected parameter values and boundary conditions are "transparent", based on solely on pumping test data and measured groundwater elevations. If different water table conditions or hydraulic conductivity values are identified, these conditions can be evaluated either qualitatively or quantitatively by re-running the model.

The model calibration assumed that the July 8, 2010 water table configuration represents a steady-state condition, so that the rate of precipitation and groundwater inflow are exactly balanced by the rate of groundwater outflow. In reality, natural aquifers are always responding to seasonal changes in precipitation and recharge. As a result, the

water table is expected to fluctuate upward and downward from the July 8, 2010 configuration. By limiting the analysis to a steady-state condition, we are assuming that seasonal changes in precipitation and recharge are not important relative to the long-term water table configuration.

Model results indicate dredging would produce a slight (1 to 2-foot) depression in the water table around the north end of the lake, and a corresponding water table rise around the south end of the lake. The lake would depress the water table at the Pioneer Meadows wells by about 0.5 feet, and water level changes at other wells would be less. Except for the Church well, none of the capture zones of surrounding water supply wells would intercept the lake. Due to the distance between the Church well and the lake (over 450 feet), no water quality impacts are anticipated at the Church well.

The model was used to calculate groundwater flow through the lake cells and through a cross section downgradient of the lake. Results indicate that flow through the lake cells would increase by about 7.7 million gallons per day (mgd) after dredging, and flow through the downgradient cross section would increase by about 4.4 mgd. Based on previous pump test results, this could cause a significant increase in the elevation of Wilder Pond. If a 200-foot dike was constructed between the north and south halves of the lake, the inflow to Wilder Pond would be reduced to about 1.5 mgd. At this rate of inflow, the rise in the pond surface elevation would be less than 1.5 feet.

Fine sediment accumulation would tend to reduce flow through the lake(s). By monitoring the rate of water level rise during dreding of the north lake, the effect of sediment accumulation can be evaluated.

A 1992 study concluded that irrigation withdrawals over 6 mgd are not stressing area aquifers, and that the potential water supply significantly exceeds actual use. With a dike between the north and south lakes, the increased flow due to dredging represents less than one-fourth of irrigation use. Considering that the water is recharged into the aquifer, the dredging activity should have little effect on the overall groundwater flow system. For comparison, the increased flow resulting from two lakes (1.5 mgd) represents about one-fifth of the mean annual flow of Wasilla Creek at Fishook Road, located approximately 10 miles upstream from the Palmer Hay Flats.

1.0 INTRODUCTION

This document provides the results of groundwater modeling at Anchorage Sand & Gravel, Inc's. (AS&G's) Palmer Pit. The purpose of the modeling effort is to resolve questions regarding the effects of gravel dredging on the underlying aquifer. As shown on Figure 1-1, the dredging operation would create a 130-acre lake up approximately 100 feet deep. A previous assessment concluded that the lake would cause a slight (1 to 2-foot) depression in the water table around the north end of the lake, and a corresponding water table rise around the south end of the lake (Brailey 2007). However, questions remain concerning the resulting lake levels and effects on nearby wells (Munter 2009). Specifically, these questions include:

- What is the expected lake level, and what effect will this have on the surrounding aquifer?
- How much flow will pass through the lake as compared with the undisturbed aquifer?
- How will the lake affect the capture zones of the Crimson View and Pioneer Meadows public water systems?
- What options are available to minimize changes to the surrounding groundwater flow system?

Figure 1-1. Proposed Lake at AS&G's Palmer Pit

A 3-dimensional groundwater model was prepared to specifically address these issues. The model is intended to be as simple as possible while still adequately representing the groundwater flow system. The model includes the effects of an uneven bedrock surface and the large pond(s) south of AS&G's property (Figure 1-1). The model does not consider transient water table fluctuations, focusing instead on steady-state flow conditions with and without the lake. Aquifer properties are based on measured values throughout most of the model domain, and assumed values for a silt formation that separates two ponds. The resulting calibration provides general agreement with the measured water table configuration, but does not reproduce local water level variations. Because the goals of the model are to address large-scale impacts surrounding the 130-acre lake, small-scale deviations from measured water table configurations were considered acceptable.

Groundwater modeling was performed using Visual MODFLOW v. 4.1, which includes MODFLOW-2000, a modular 3-dimensional finite-difference groundwater flow model developed by the U.S. Geological Survey (USGS; Harbaugh et al. 2000). Visual MODFLOW also includes MODPATH and Zone Budget, two USGS programs to calculate particle pathlines and subregional water budgets, respectively.

The following sections describe the regional geology and hydrology, model grid and boundary conditions, steady state calibrations, and predictive modeling results.

2.0 REGIONAL GEOLOGY AND HYDROLOGY

The Matanuska valley near Palmer is bounded by the Talkeetna Mountains on the north and the Chugach Mountains to the south and east (Figure 2-1). The Matanuska valley was formed by repeated glacial advances along a zone of faulting and deformation between metasedimentary and metaigneous rocks the Chugach Terrane on the south and granitic and sedimentary rocks the Peninsular Terrane on the north. Bedrock is exposed at the surface along the fronts of the Talkeetna and Chugach mountains, and is mantled by alluvium on the valley floor. The thickness of alluvium varies considerably, ranging up to over 200 feet near the center of the "Palmer terrace" (Pewe and Reger 1983; Figure 2-2). Local bedrock highs occur at Bodenburg Butte, a constriction of the Matanuska River near Palmer, and in the western part of the AS&G property (Figures 2-1 and 2-2).

Figure 2-1. Regional Geologic and Hydrologic Setting

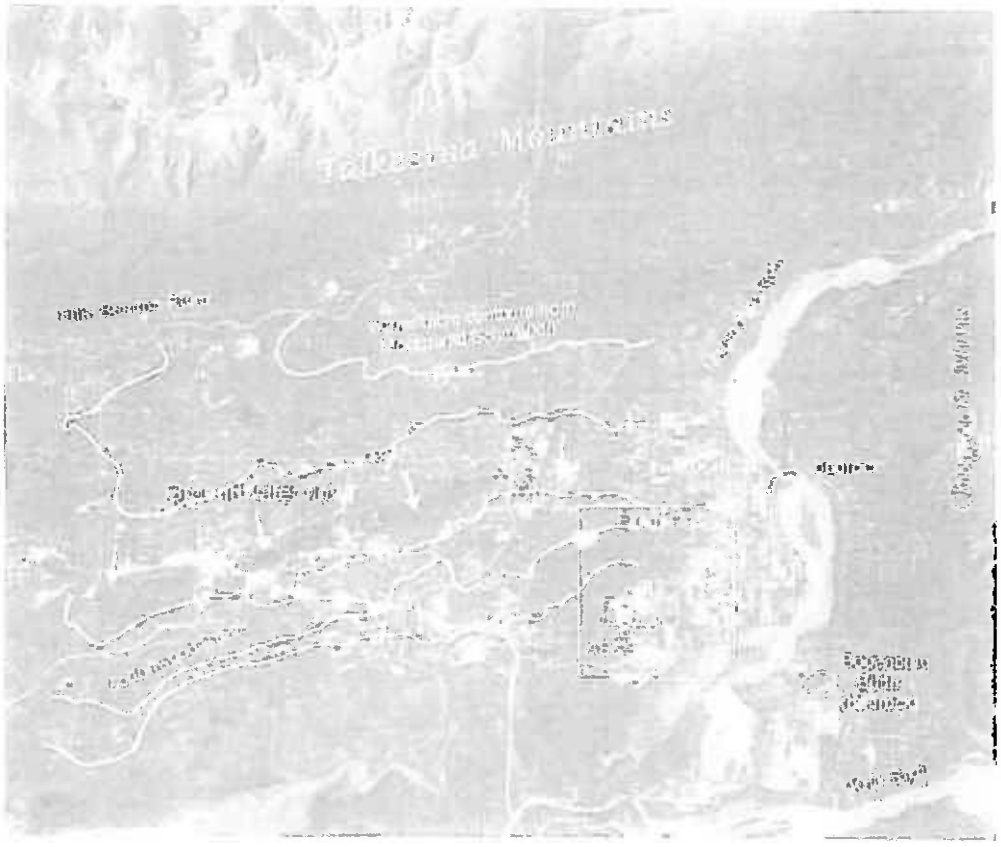

Figure 2-2. "Palmer terrace" and Crevasse-Fill-Ridge Deposits

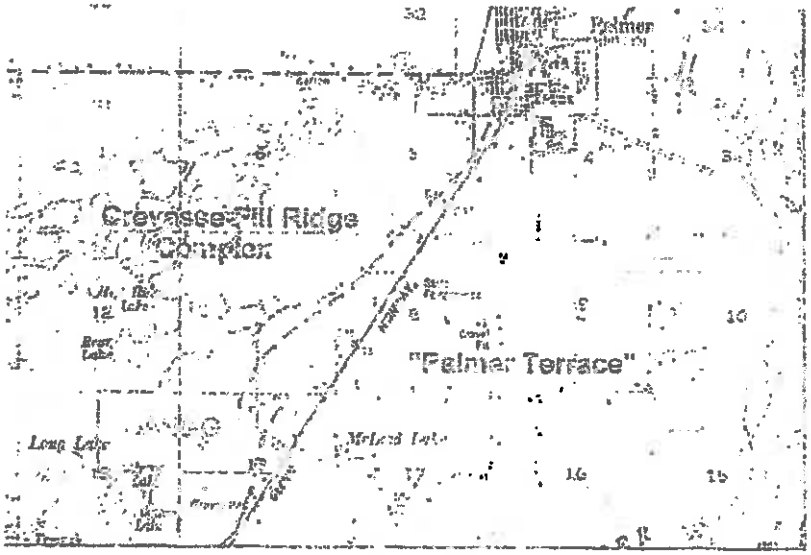

AS&G's Palmer Pit is located in crevasse-fill-ridge deposits located immediately west of the "Palmer terrace" (Pewe and Reger 1983). These deposits formed in subparallel crevasses that developed in stagnant ice during the later stages of the Naptowne Glaciation. Although most of the ridges are comprised of marketable sand and gravel (Figure 2-3), one ridge on the west side of Wilder Pond contained a silt lens that

Figure 2-3. Typical Crevasse-Fill-Ridge Deposit, Palmer, Alaska

separated the dredge pond from a topographically depressed area to the west. The silt lens was breached in July 2004, causing flooding of the depressed area and lowering of the dredge pond by as much as 7.6 feet (Figure 2-4).

Figure 2-4. Wilder Pond in 2003 vs. 2006

The "Palmer terrace" was deposited slightly after the crevasse-fill-ridge deposits, as the Naptowne ice front retreated to the north. These outwash deposits locally overlie the crevasse-fill-ridge sediments in the vicinity of the Palmer Pit (Pewe and Reger 1994).

Based on a regional water table map prepared by the U.S. Geological Survey (Moran and Solin 2006), groundwater flow is generally southward from the Talkeetna Mountain front (Figure 2-1). In the vicinity of the Palmer Pit, groundwater occurs in an unconfined aquifer tapped by numerous domestic and community water supply wells (Figure 2-5). The aquifer is relatively thick (locally over 200 feet) and commonly exhibits high well yields. Comparison of the water table elevation with adjacent floodplain elevations (Figure 2-2) suggests that the unconfined aquifer is recharged by both the Matanuska River and by groundwater inflow from the north. Oxygen isotope studies performed by the U.S. Geological Survey indicate that the water table aquifer

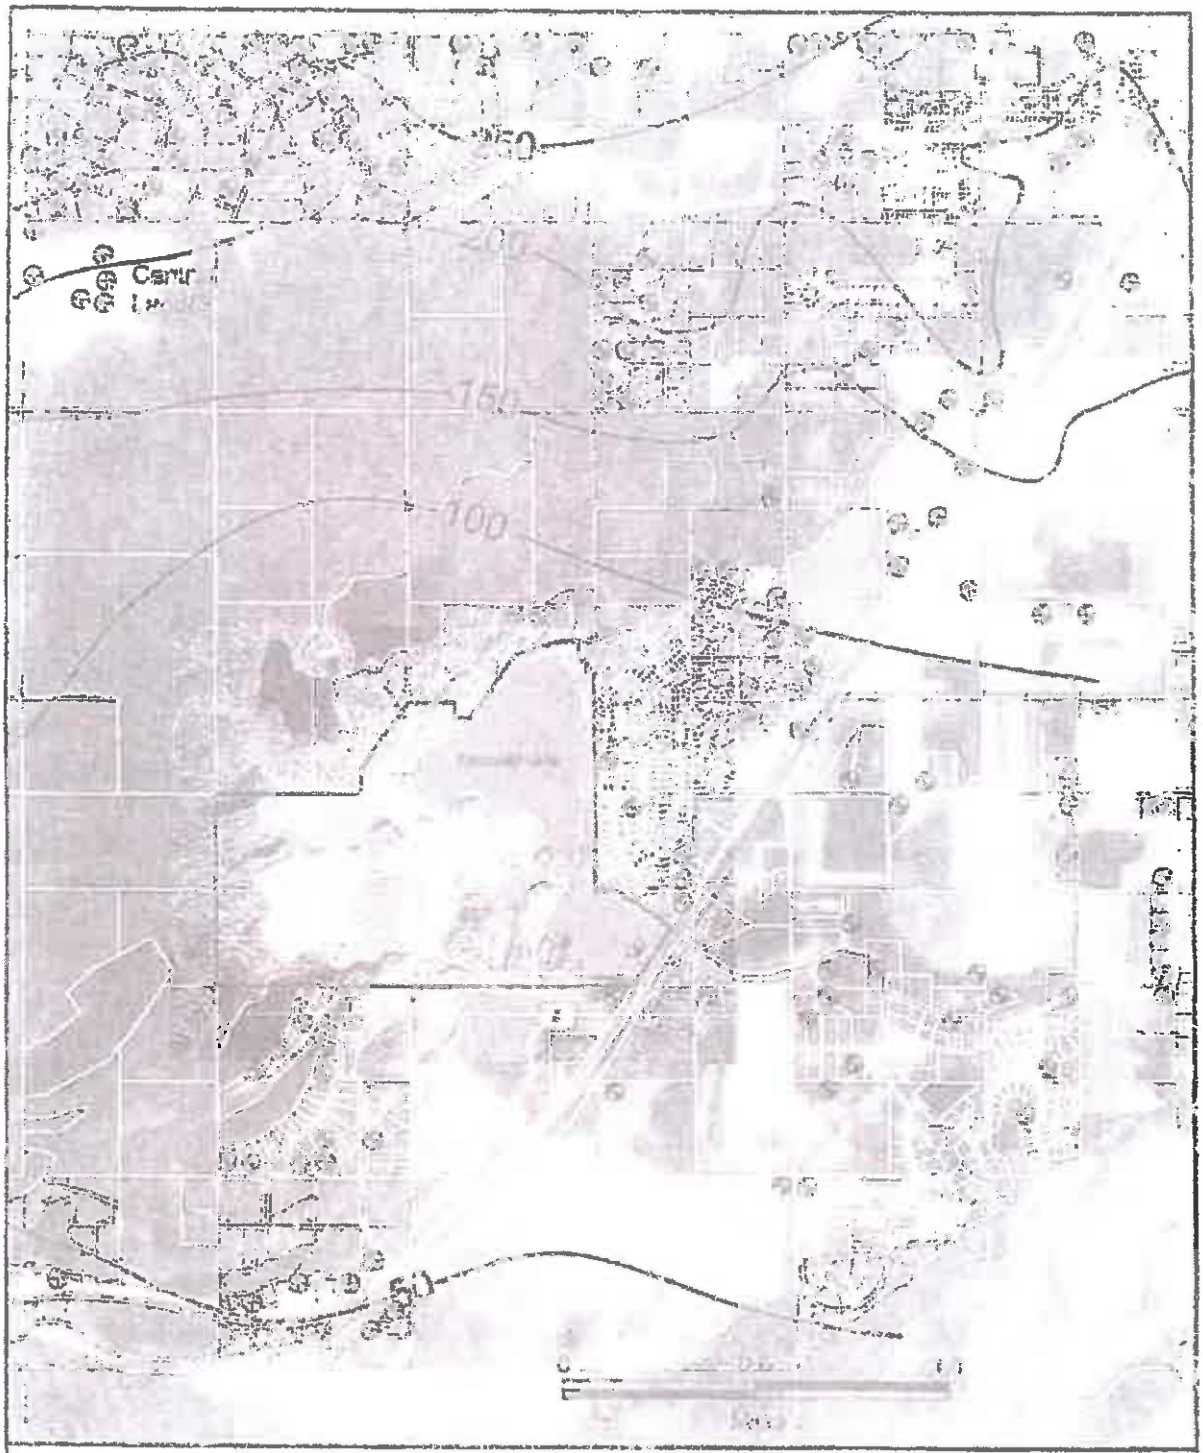

Figure 2-5. Water Table in the Vicinity of AS&G's Palmer Pit

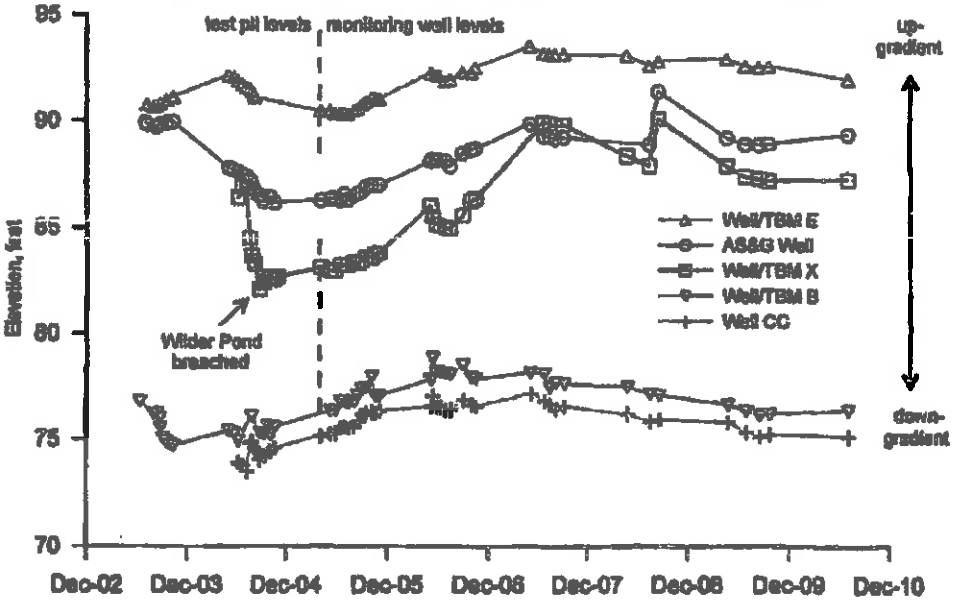
Brailey Hydrologic Consultants
August 2010

has a direct hydraulic connection to many lakes in the Palmer-Wasilla area (Moran and Solin 2006).

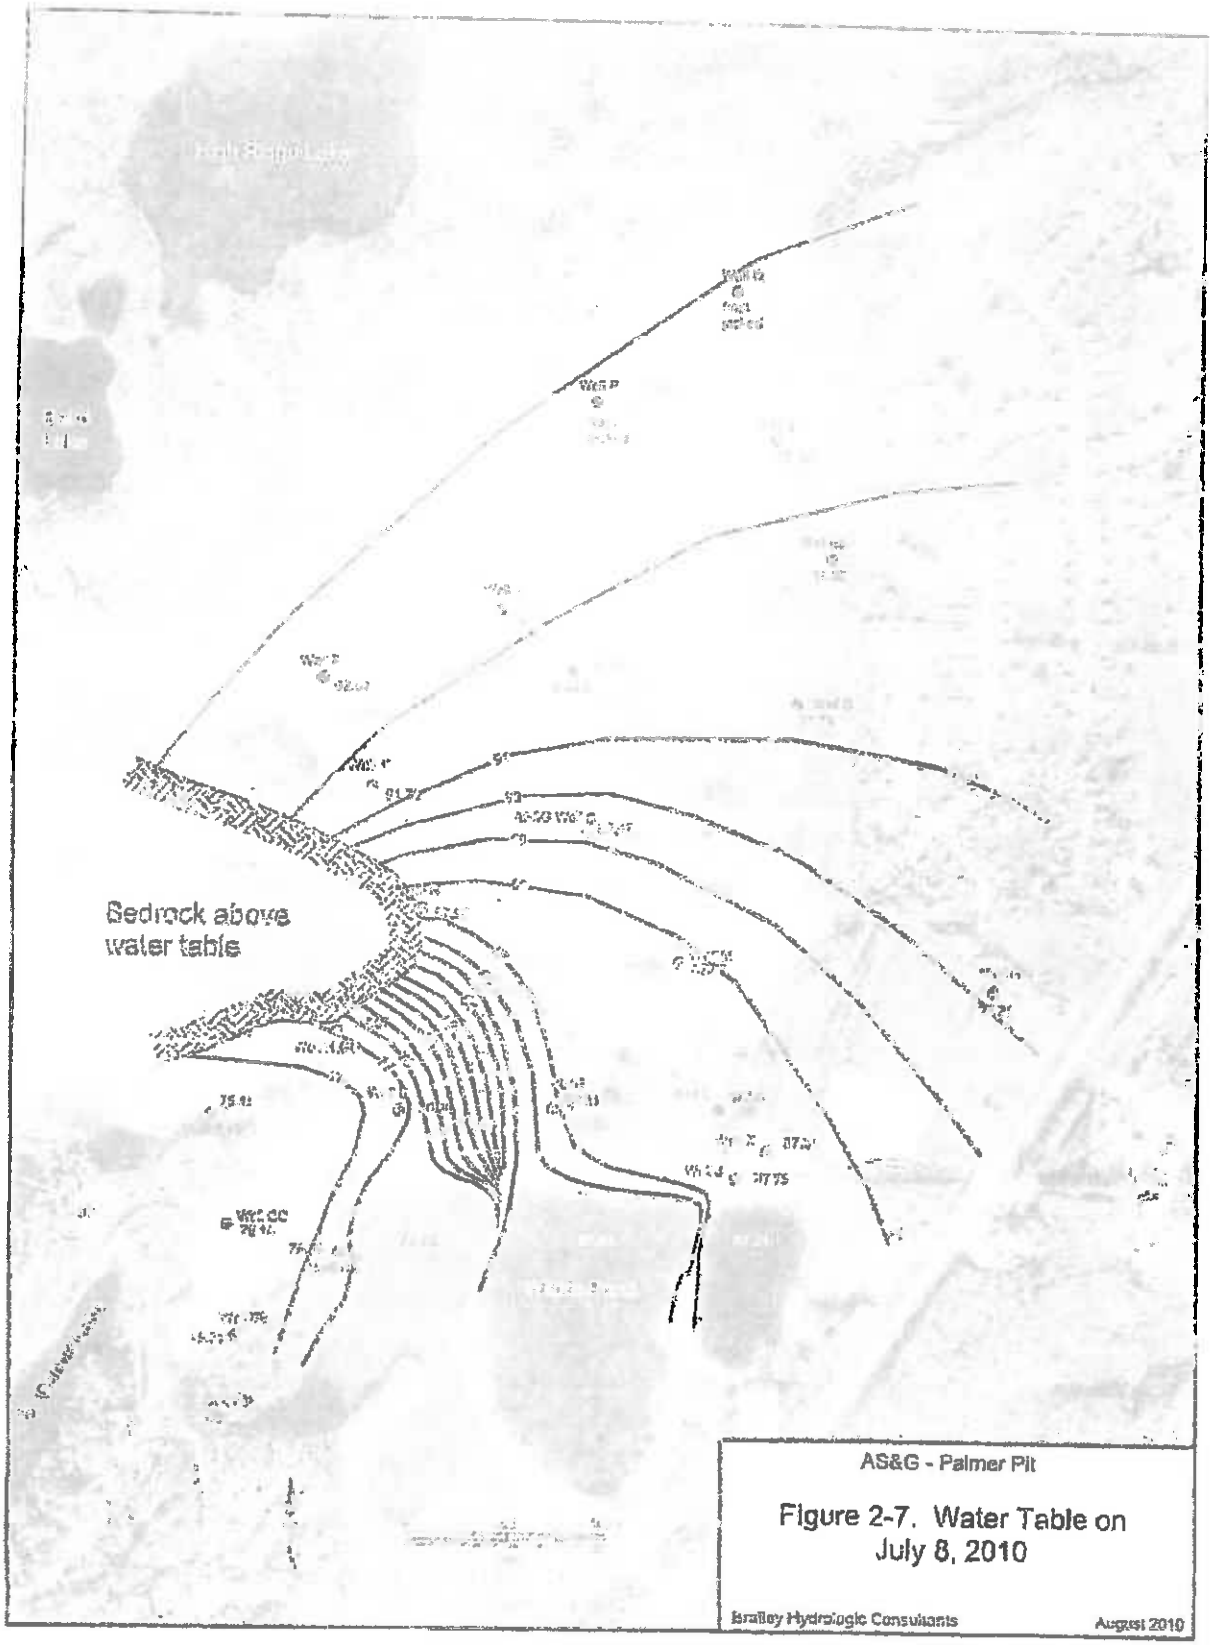
AS&G has performed periodic water level measurements at the Palmer Pit since 2003 (Figure 2-6). The initial monitoring network included a number of test pits that were replaced with monitoring wells in 2005. The current monitoring network includes 19 PVC monitoring wells, three inactive steel-cased wells, and an active domestic well. Water levels in the central Wilder Pond were monitored from 2003 to 2005, but were not available for the east and west ponds until July 2010. Similarly, concurrent water level elevations for Canoe and Irene Lakes were not available until July 2010.

Including water surface elevations for Irene Lake and the three adjacent dredge ponds, the July 8, 2010 water table configuration reflects the most complete set of water level measurements in the monitoring database. Long-term hydrographs show that the July 8, 2010 water table configuration elevation is relatively stable, having adjusted to the adjacent dredge ponds excavated in 2002 through 2007 (Figure 2-6).

Figure 2-6. Long-term Hydrographs, AS&G Monitoring Wells



The July 8, 2010 water table configuration shows a generally southward groundwater flow direction that curves around a bedrock high separating Baird and High Ridge Lakes to the north from Canoe and Irene Lakes to the south (Figure 2-7). Based on



Bedrock above
water table
AS&G - Palmer Pit
Figure 2-7. Water Table on
July 8, 2010
Bradley Hydrologic Consultants
August 2010

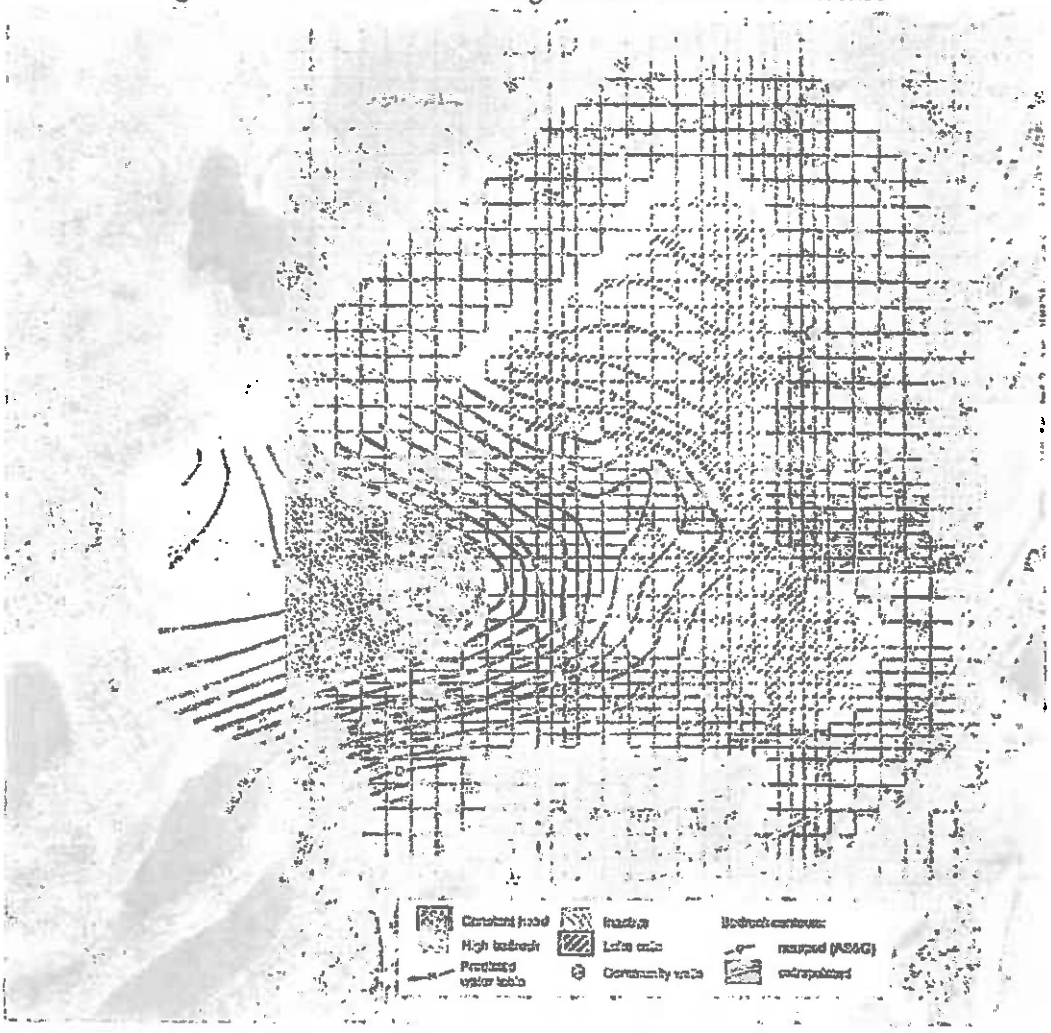
aerial photogrammetric measurements (AeroMetric 2008), the elevation difference between Baird and Irene Lakes is about 25 feet. Although the surface of Canoe and Irene Lakes is about 5 feet above the water table, the slope of the water table is consistent with the elevation difference between the lakes north and south of AS&G's property. The difference between the water table elevation and the surface of Canoe and Irene Lakes suggests that the lakes are perched by fine grained sediments lining the bottoms of the lakes. Perching of lakes and streams has long been recognized in the groundwater literature, and is commonly modeled using a reduced lake or streambed conductance relative to the underlying deposits (e.g. Merritt and Konikow 2000).

- Although the unconfined aquifer generally flows southward toward discharge areas along the Matanuska River (Munter 2010), the lowest groundwater elevations occur in the southwest corner of AS&G's property (Figure 2-7). This suggests a zone of increased transmissivity south of Canoe Lake. By analogy with Echo and Kepler Lakes, Canoe and Irene Lakes were once occupied by stagnant ice masses separated by meltwater streams (Reger and Updike 1983). Flow constrictions between the stagnant ice masses could have resulted in high-permeability zones between the lakes. Fine-grained sediments and a former pond at the location of Wilder's central pond (Figure 2-2) suggest that an ice mass was present in this area. If so, meltwater flows could have been constricted between this area and the ice mass in Canoe Lake, resulting in a buried channel of high-permeability deposits.

3.0 MODEL GRID AND BOUNDARY CONDITIONS

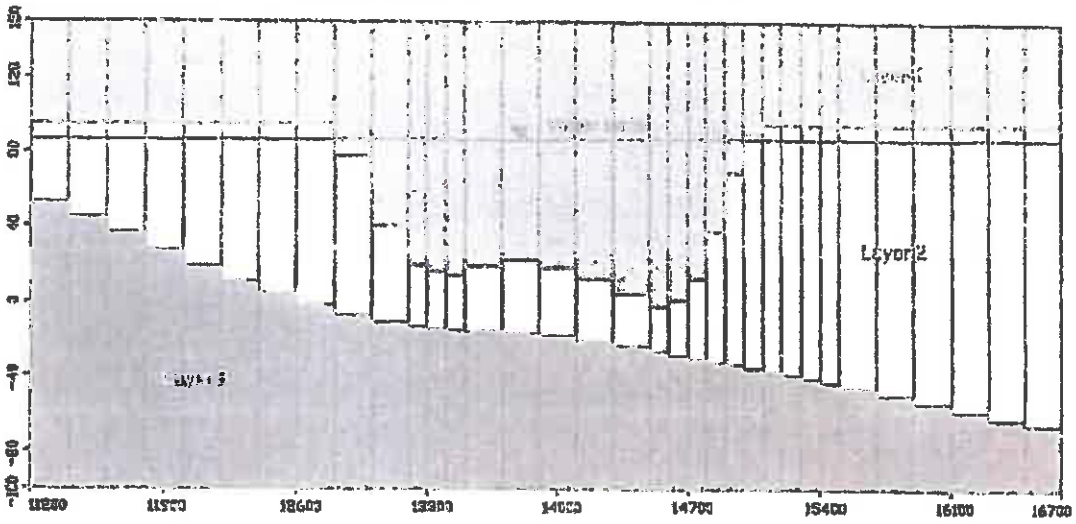
As proposed in AS&G's *Groundwater Modeling Plan* (Brailey 2009), the model grid is oriented north-south, approximately parallel to the regional groundwater flow direction (Figures 2-1 and 2-4). The grid includes three layers, each consisting of 43 rows and 34 columns. The bottom layer (Layer 3) represents bedrock, simulated using inactive cells. Geologic mapping performed by AS&G indicates a bedrock ridge beneath the western part of AS&G's property, where bedrock elevations extend up to 30 feet above the water table. The bedrock elevation is well-defined in the center and west of the model area, but required extrapolation to the north, east, and south (Figure 3-1).

Figure 3-1. Model Grid Showing Bedrock Elevation Contours



The middle layer (Layer 2) represents aquifer materials that will not be disturbed by mining, and the top layer (Layer 1) represents materials that will be removed (Figure 3-2). The model was calibrated using the same hydraulic conductivity for Layers 1 and 2, representing hydrologic conditions before mining. The effect of gravel dredging was simulated by increasing the hydraulic conductivity of Layer 1 until all of the "lake" cells exhibited the same head. This provides an unbiased estimate of the lake elevation, dependent only calculated water flows into and out of the lake.

Figure 3-2. Model Cross Section: Row 13



The model's lateral boundary conditions are illustrated on Figure 2-1. Except where bedrock elevations are above the water table, the perimeter of the model is a constant head boundary with head values estimated from water table maps of the monitoring network.

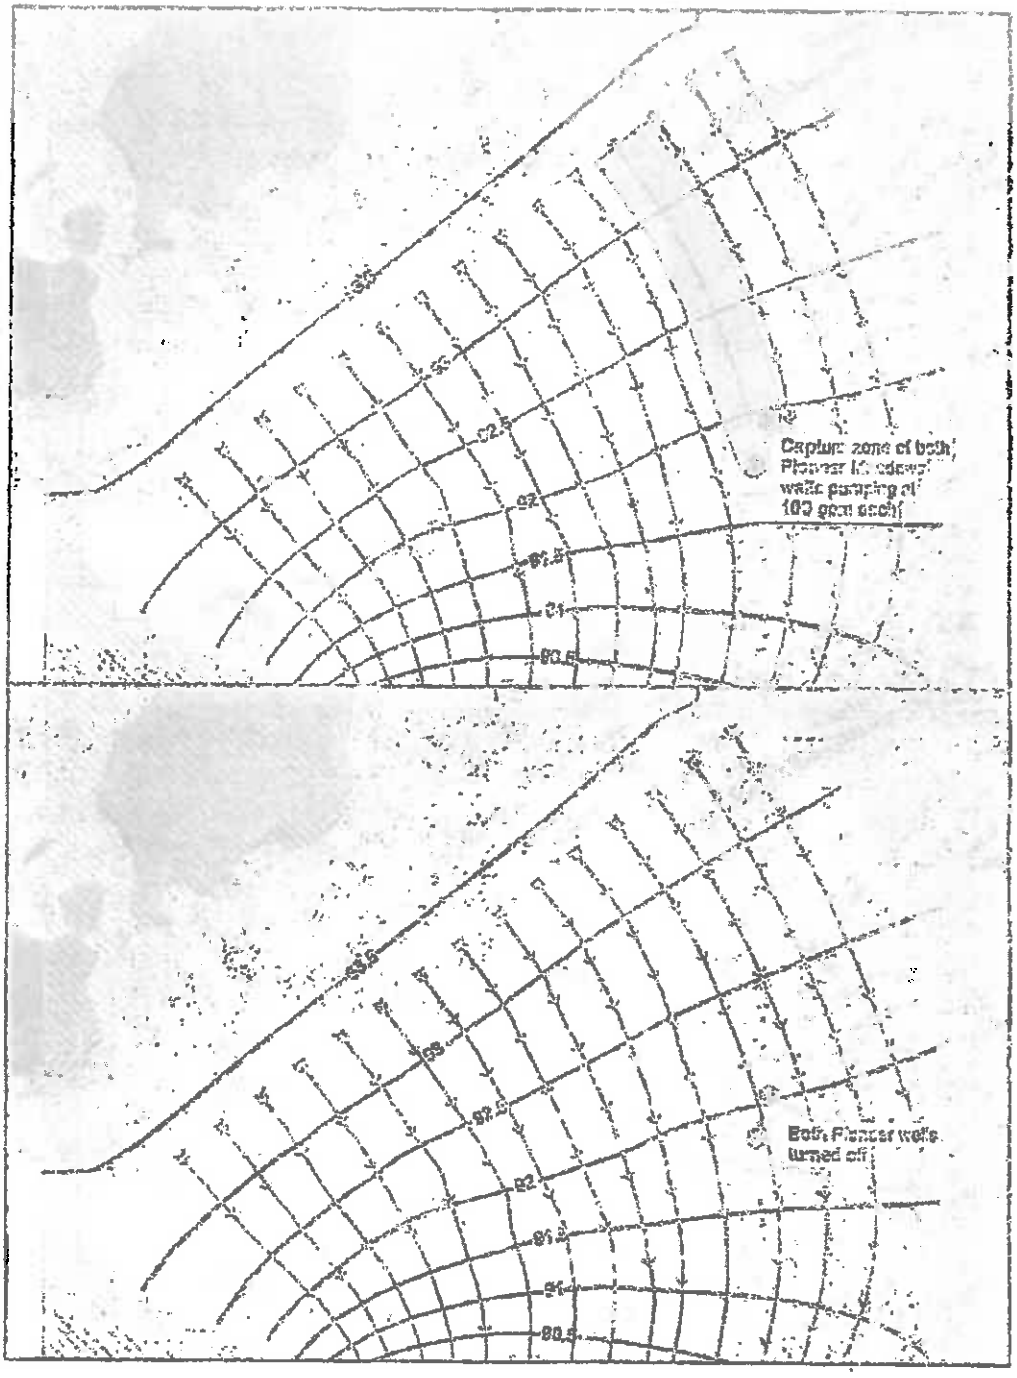
Groundwater recharge from precipitation was included by specifying a recharge rate of four inches per year throughout the model domain. This represents about one-fourth of annual precipitation, and is consistent with recharge values estimated by Patrick and others (1989) for lower elevations in the Anchorage Bowl. Modeling results indicate that recharge from precipitation is a relatively small component of the overall water balance.

A final boundary condition was included to assess the impact of water supply wells on the local groundwater flow system. There are five domestic wells and two community water supply systems within the model domain. The Pioneer Meadows community

water supply system served 86 residents in 2001, and the Crimson View community supply system served 120 residents in 1998. The five domestic wells serve individual homes.

To evaluate the effect of water supply wells, two pumping wells were added at locations corresponding to the Pioneer Meadows wells (Figure 3-3). These wells are located such that the constant head boundary has little effect on modeled drawdown and flowlines. In contrast, the Crimson View well is located immediately adjacent to a constant head boundary. The Pioneer Meadows wells were both assigned continuous pumping rates of 100 gallons per minute (gpm), for a combined flow rate nearly ten times the Crimson View system's peak daily production for 2001. Even at these pumping rates, the model results demonstrate that the Pioneer Meadows wells have little effect on the groundwater flow system (Figure 3-3). By analogy, the Crimson View well and the five domestic wells should have little effect on the goals of the modeling effort.

Figure 3-3. Effect of the Pioneer Meadows Wells Pumping at 100 gpm Each



4.0 MODEL CALIBRATION

AS&G's *Groundwater Modeling Plan* proposed fitting the model to measured water table configurations during and after a June 2004 pumping test of Wilder Pond, using the measured pumping rate (3,300 gpm) as an additional boundary condition. Two sets of water level measurements were recorded during this period, on June 12 and June 27, 2004. As shown on Figures 4-1 and 4-2, other water level changes (unrelated to pumping) also occurred between June 12 and 23, 2004. Because the non-pumping water level changes had a significant effect on the flow rate entering Wilder Pond, the measured pumping rate could not be reproduced within reasonable parameter limits.

However, an acceptable steady-state calibration was obtained using water level measurements on July 8, 2010 (Figure 4-3). In addition to the wells measured in June 2004, the July 8, 2010 measurements included several data points near AS&G's south property boundary, including Wells H and I, the three dredge ponds south of AS&G's property, and Irene Lake. Long-term hydrographs show that the July 8, 2010 water table configuration elevation is relatively stable, having adjusted to the adjacent dredge ponds excavated in 2002 through 2007 (Figure 2-6).

Based on consistent pump test results for Wilder Pond and the AS&G Well (Appendix A), the July 8, 2010 calibration assumed a regional hydraulic conductivity of 1,400 ft/day, with a lens of reduced hydraulic conductivity paralleling Canoe and Irene Lakes (Figure 4-3). A pump test performed on Well I (Appendix A) indicates a local hydraulic conductivity of 50 ft/day on the east side of the lens, and the 8-foot difference in water levels suggests an even lower hydraulic conductivity between Wilder's central and western dredge ponds. Accordingly, the lens was assigned an hydraulic conductivity of 50 ft/day near Well I and 10 ft/day between Wilder's central and western dredge ponds. This hydraulic conductivity distribution results in an average error of +1.22 feet in predicted water table elevations west of the low permeability lens, and an average error of +0.14 feet elsewhere throughout the model. The model error west of the low permeability lens could be reduced by further increasing the local hydraulic conductivity, but this result has little effect on model outcomes.

5.0 PREDICTIVE MODELING RESULTS

Predictive modeling runs were performed using the July 8, 2010 water table configuration, reflecting the current dredge pond geometry south of AS&G's property. The model runs were performed assuming steady-state conditions, which does not account for seasonal water table fluctuations or variations in pumping and recharge rates. Nevertheless, the steady-state runs illustrate the general groundwater flow changes that can be expected after dredging of the lake.

The effect of the lake was simulated by increasing the hydraulic conductivity of Layer 1 until all of the lake cells showed the same head value. In the lake's original configuration, convergent solutions were obtained using Layer 1 hydraulic conductivities up to 10,000,000 ft/day, resulting in lake head values that agreed to within 0.01 feet. However, subsequent dredging plans involved a 20 percent expansion of the south half of the lake. In this configuration, convergent solutions could only be obtained for Layer 1 hydraulic conductivities up to 5,000,000 ft/day. This configuration results in a 0.08-foot head difference between the north and south halves of the lake (Figure 5-1). In reality, there would be no difference in water surface elevations between the two ends of the lake. The 0.08-foot head difference reflects the Layer 1 hydraulic conductivity needed to achieve a convergent solution (5,000,000 ft/day), which provides more resistance to flow than an open channel. Although slightly inaccurate from a surface water standpoint, this difference does not affect the accuracy of modeled groundwater elevations and flow quantities. Rather, the modeling approach provides an unbiased estimate of the resulting lake elevation.

The modeled water table contours indicate that groundwater would enter the north half of the lake and exit via the south half (Figure 5-1). Comparison of modeled groundwater levels indicates that the lake would reduce the water table elevation at the Pioneer Meadows wells by about 0.5 feet. Because these wells are both 100 feet deep and have static water levels ranging from 27 to 30 feet (ADNR 2010), the lake would not affect their well yields. Likewise, because flow is toward the north half of the lake (Figure 5-1), the lake would not affect their water quality. Although the Crimson View well is too close to the model boundary for accurate simulation, its location suggests that there would be no change in well yield or water quality.

The closest domestic well downgradient of the proposed lake is the Church well, located approximately 450 feet from the lake's southeast corner (Figure 5-1). The presence of domestic wells between Canoe and Irene Lakes suggests that the aquifer provides

adequate filtration over horizontal distances much smaller than 450 feet. As a result, no water quality impacts are expected at the Church well.

The rate of groundwater flow through the lake was calculated using MODFLOW's Zone Budget module (Harbaugh 1990). Groundwater flow was calculated through the lake cells and through a cross section downgradient of the lake (Figure 5-1). The downgradient cross section was divided into two segments, one discharging into Wilder Pond and another discharging towards Canoe and Irene Lakes. The results shown on Table 5-1 indicate that the lake cells would transmit about 11 million gallons per day (mgd) after dredging, as compared with about 3 mgd under current conditions. Flow through the downgradient cross section would increase from 6.8 to 11 mgd, with most of the discharge entering Wilder Pond.

Table 5-1. Zone Budget Results

Dredging Option	Flow through Lake Cells (mgd[1])	Flow through Downgradient Cross Section, mgd[1]				
		West Segment	East Segment	Total	Increase Over Baseline	Percent Increase
Baseline conditions	3.0	1.6	5.2	6.8		
One Lake	10.7	1.7	9.5	11.2	4.4	65
Two Lakes	9.7	1.6	6.6	8.3	1.5	22
North Lake Only	6.2	1.6	5.6	7.2	0.5	7.0

1 mgd = million gallons per day

Although the model boundary requires a constant water level in Wilder Pond, pump test results (Appendix A) indicate that the increased flow would raise the pond level. By maintaining a lower pond elevation, the model boundary overestimates pond inflow. Nevertheless, it appears that a single lake on AS&G's property could cause a significant increase in the elevation of Wilder Pond. To reduce the inflow into Wilder Pond, a dike could be constructed between the north and south halves of the lake (Figure 5-2). Using an hydraulic conductivity of 10 feet/day, a 200-foot dike would reduce the inflow into Wilder Pond to about 1.5 mgd. Comparison with the June 2004 pump test results indicates that the additional inflow would raise the Wilder Pond level by about 1.5 feet. If dredging was limited to the north lake only, the additional inflow into Wilder Pond would be about 0.5 mgd, resulting in a pond level increase of about 0.5 feet.

La Sage (1992) noted that the Palmer city wells are permitted for withdrawal of 2 mgd, and that irrigation use probably exceeds 6 mgd. Based on analysis of water level records, La Sage concluded that these withdrawals are not stressing area aquifers, and that the potential water supply significantly exceeds actual use. With a dike between the north and south lakes, the increased flow due to dredging (1.5 mgd) represents less than one-fourth of 1992 irrigation use. Considering that the water is recharged into the aquifer, the dredging activity should have little effect on the overall groundwater flow system.

For comparison, the increased flow resulting from two lakes (1.5 mgd) represents about one-fifth of the mean annual flow of Wasilla Creek at Fishook Road, located approximately 10 miles upstream from the Palmer Hay Flats.

The foregoing analyses assume that flow into and out of the lake will not be affected by fine-grained sediments accumulating on the lake bottom. In reality, most natural and man-made lakes develop a sediment lining that reduces groundwater exchange. For example, the water surface of Canoe Lake is perched approximately 5 feet above the water table, indicating that fine-grained sediments limit outflow into the aquifer. The dredging process will suspend fine-grained sediment in the water column, which will settle onto the lake bottom as dredging proceeds. The rate and thickness of sediment accumulation is unknown, but it will likely reduce both inflow and outflow.

AS&G plans to dredge the lakes in a north-to-south direction over a 15- to 20-year period. During this time, water levels will be monitored regularly and compared against the rate of increase predicted by the model (Figure 5-3). The resulting data will be used to assess the effect of sediment accumulation and to monitor for unforeseen adverse effects. Mitigating steps will be implemented if the data indicate any potential future problems.

APPENDIX A – GROUNDWATER PUMPING TESTS

Although the modeled water table geometry is primarily controlled by the configuration of the surrounding constant head boundary, the rate of groundwater flow through the model is dependent on the aquifer's hydraulic conductivity. To determine representative hydraulic conductivity values, groundwater pumping tests were performed on Wilder Pond and two wells located on AS&G's property. These tests are described in the following sections.

A.1 June 2004 Pumping Test on Wilder Pond

In preparation for subsequent dredging activities, Wilder Construction performed a pumping test on Wilder's central pond in June 2004. The pond was reportedly up to 200 feet deep, and was separated from a previously mined area to the west by a silt dike (Figure A-1). The silt dike was sufficiently impermeable to prevent seepage into the mined area, which was depressed up to 8 feet below the pond surface elevation. To evaluate the effect of breaching the dike (Figure 2-4), water was pumped from the central pond to another location on Wilder's property. According to flow measurements performed by Wilder, the pond was pumped at a constant rate of 3,300 gpm for 7 days. The decline in water levels due to pumping was measured using pressure transducers installed in Wilder Pond and Well AA (Figure A-2).

Figure A-1. Wilder Pond Extents, October 2003

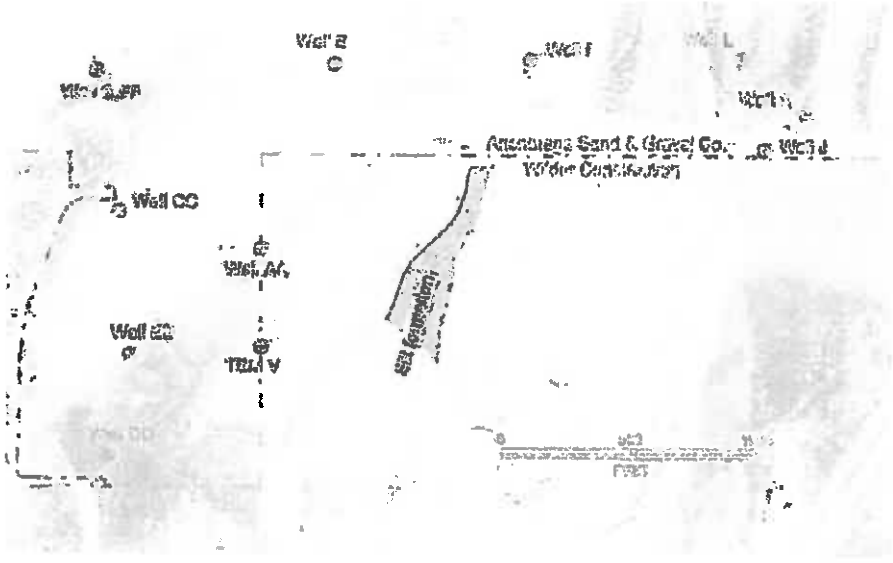

Figure A-2. Water Levels in Wilder Pond and Well AA

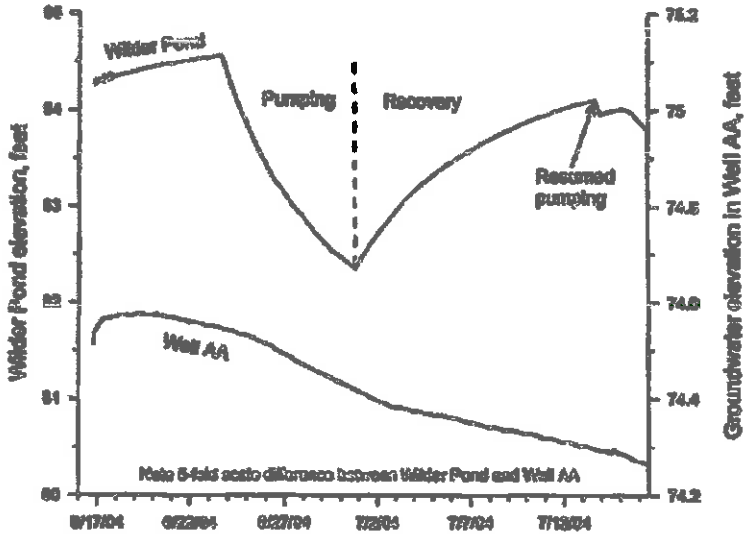
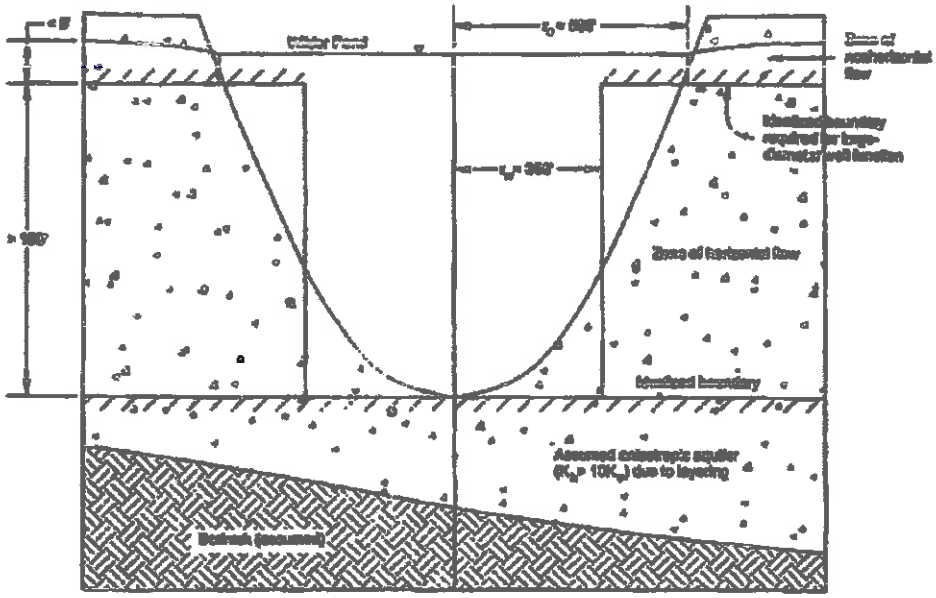


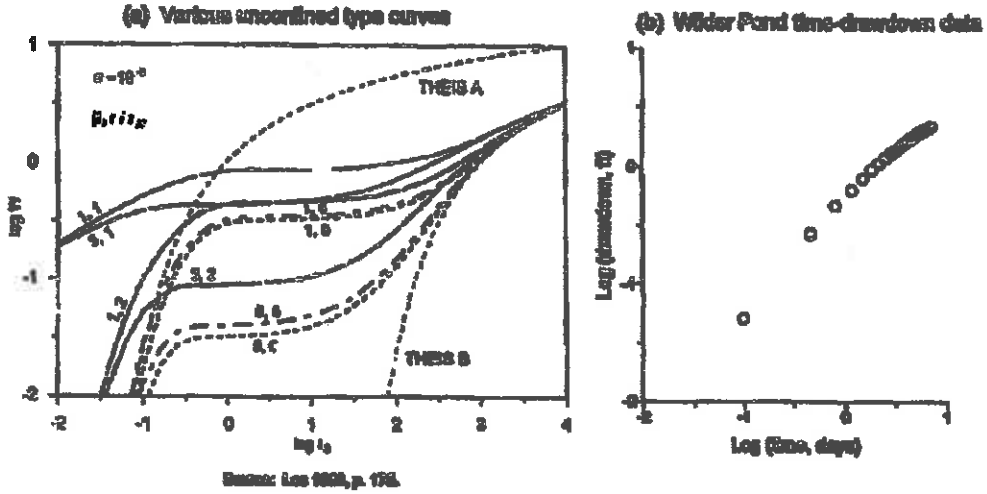
The pumping test data were analyzed using type curves for flow to a large diameter well developed by Mishra and Chachadi (1985). This approach requires the assumed geometry shown on Figure A-3, where the pond is considered to be cylindrical. The sloping sidewalls of the pond are simulated using the parameter α, defined as $\phi (r_w/r_c)^2$ where ϕ is porosity and r_w and r_c are the radial dimensions shown on Figure A-3. The

Figure A-3. Idealized Geometry for $\alpha = 0.1$



aquifer is assumed to be confined, with no vertical component of flow. Although the aquifer is actually unconfined, the time-drawdown curve does not show the delayed gravity response characteristic of unconfined aquifers (Figure A-4). This suggests that the effect of gravity drainage is negligible relative to horizontal flow, and water is released from the aquifer predominantly via confined aquifer mechanics. Evidence for this type of response in unconfined aquifers is discussed further by Neuman (1974).

Figure A-4. Time-Drawdown Data vs. Unconfined Type Curves



The pumping test data were evaluated by superimposing a log-log plot of drawdown vs. the reciprocal of time on type curves provided by Mishra and Chachadi (Figures A-5 through A-7). Type curves are provided for different values of α, defined as:

$$\alpha = \phi \left(\frac{r_w}{r_c} \right)^2 \qquad (1)$$

where ϕ is porosity and r_w and r_c are the radial dimensions shown on Figure 3. Selecting ψ as the x-axis value corresponding to the duration of pumping (t_p), transmissivity was calculated as:

$$T = \frac{\phi r_w^2}{4 t_p \psi} \qquad (2)$$

For each value of α, a different value of r_w was calculated by rearranging Equation (1). Results are summarized on Table A-1.

Figure A-5. Curve Fit of Pumping Test Data for $\alpha = 0.01$

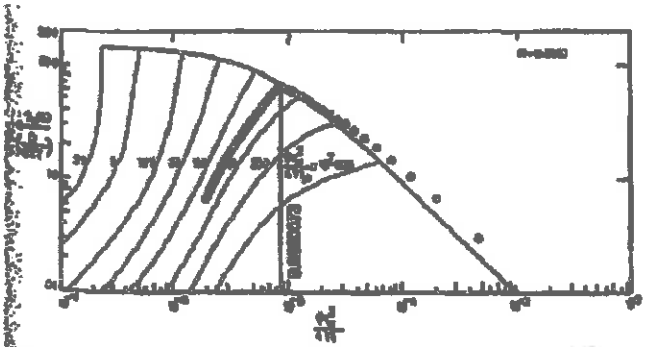

Fig. 2(d). Family of type curves: $S_{yy}(t)/(Q/4\pi T)$ versus $r_w^2/4Tt$ for $\alpha = 10^{-4}$.

Table A-1. Wilder Pond Transmissivity Calculations

Parameter	Source	Curve Fit #1 (Figure A-5)	Curve Fit #2 (Figure A-6)	Curve Fit #3 (Figure A-7)
Porosity, ϕ	Estimated	0.25	0.25	0.25
Pond radius, r_c	[Area/π] $^{1/2}$	566 feet	566 feet	566 feet
Deep radius, r_w	from (1)	113 feet	35.8 feet	11.3 feet
Duration of pumping, t_p	Transducer data	7.1 days	7.1 days	7.1 days
x-axis value at t_p, u	curve fit	0.0009	0.00008	0.0000073
Transmissivity, ft²/day	from (2)	125,335	141,002	154,522

Comparison of Figures A-5 though A-7 suggests that the best fit of pumping and recovery test data was obtained for α = 0.001 (Figure A-6), indicating an aquifer transmissivity of about 141,000 ft²/day. Assuming an aquifer thickness of 200 feet, this result corresponds to an hydraulic conductivity of 700 ft/day. However, this result assumes that flow is fully radial throughout the surrounding aquifer. In contrast, the silt lens west of Wilder Pond constitutes an hydraulic barrier that was sufficiently impermeable to prevent seepage into the adjacent depression (Figure A-2). This configuration is similar to a well located near an impermeable boundary, which is evaluated in detail by Bear (1979). For the case of a well located immediately adjacent to an impermeable boundary, the measured drawdown should be twice the drawdown in an equivalent unbounded aquifer. Because drawdown is inversely related to hydraulic conductivity, reducing drawdown by half (while maintaining a constant flow rate) is mathematically equivalent to doubling hydraulic conductivity. Thus, the actual hydraulic conductivity should be twice the value obtained using the foregoing radial flow model, or about 1,400 feet per day. If the silt lens is somewhat leaky, then the actual hydraulic conductivity may be somewhat less.

A.2 May 2010 Pumping Test on the AS&G Well

To confirm that the hydraulic conductivity on AS&G's property is comparable to that measured at Wilder Pond, a pumping test was conducted on the "AS&G Well" on May 14, 2010. Along with Wells M and N, the AS&G Well is one of three steel-cased wells in the center of the AS&G property (Figure 2-5). A well log is not available for this well,

but it is 80 feet deep, with a static water level about 30 feet below ground surface. Local knowledge indicates that well has not been used since the mid-1980's, and that it may have been a high-yield well used for gravel washing operations.

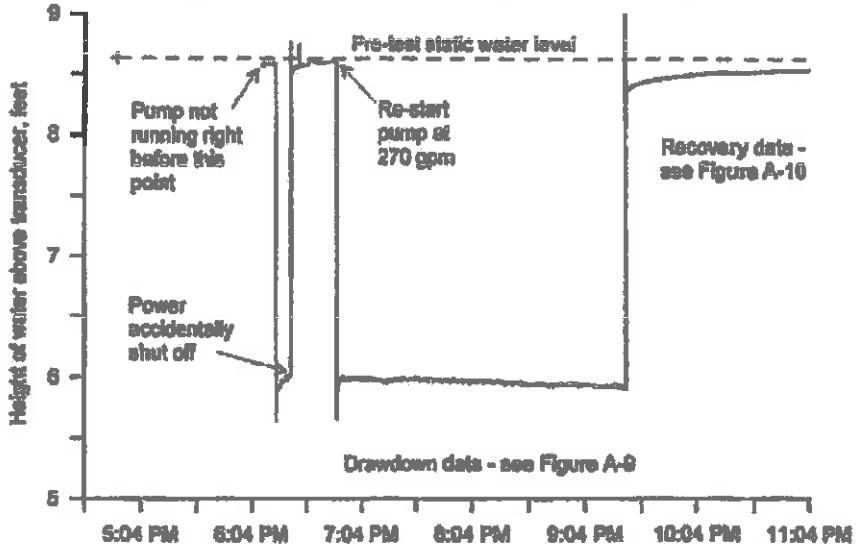
The AS&G Well is 8 inches in diameter, but has no pump or power supply. It is not known if the well is screened, perforated, or open-ended. This information is important for analysis of measured drawdowns in the pumping well, which can be exaggerated if flow is restricted as it enters the well. For this reason, additional observation wells were considered for measurement of drawdown outside the pumping well. However, the small drawdowns reported for the adjacent Pioneer Meadows wells (AWPS 2010) raised concern that drawdown might not be measurable outside the pumping well. As a result, a single-well pumping test was planned prior to installation of any observation wells.

During single-well pump tests, drawdowns in the pumping well can be affected by friction losses and by pump turbulence. However, the rise in water level after the cessation of pumping (termed recovery) can also be used to determine hydraulic conductivity. Although early-time recovery data can be affected by friction losses, the pumped well rapidly equilibrates with water levels outside the well casing, so that intermediate- and late-time recovery data reflect water levels in the surrounding aquifer. The longer the well is pumped (and the higher the pumping rate), the larger the cone of depression becomes outside the pumping well. The use of intermediate- and late-time recovery data minimizes the effect of friction losses, and provides a measure of hydraulic conductivity at a larger radial distance from the well.

Based on high nearby well yields, Anchorage Well and Pump Service installed a 30-horsepower turbine pump on May 14, 2010. The pump was powered by a 160 kilowatt (kW) generator providing 3-phase, 460-volt power. The pump was connected with four inch-diameter pipe to a totalizing flowmeter and a hose discharging downslope from the pumped well. During the test, the discharge flowed over the ground surface to the pit floor approximately 400 feet northwest.

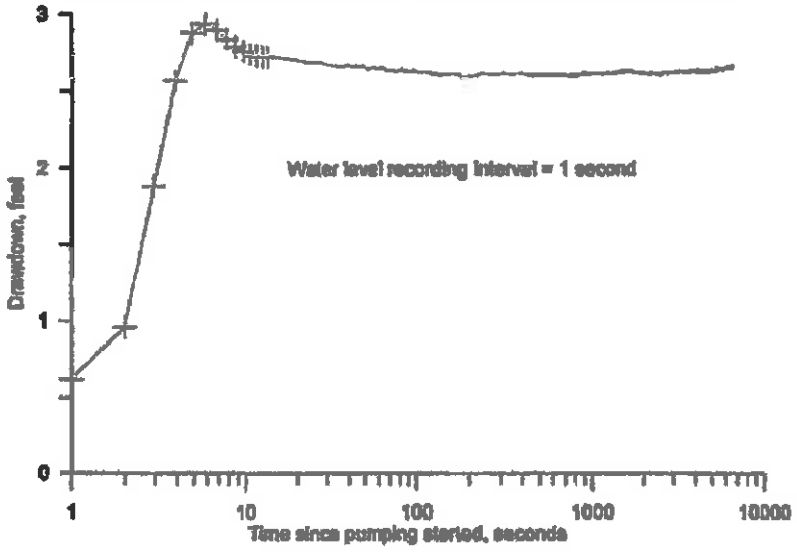
The water level in the pumped well was measured with a 5-psi pressure transducer suspended about 8 feet below the static water level. Figure A-8 shows a summary of water levels measured during pumping and the first 2 hours of recovery. The pump was first energized at 5:10 pm, but it produced only about one-tenth of its rated discharge (~300 gpm). The pump was turned off and on several times between 5:10 and 6:10 pm, during which it was determined that the pump impellers may have been plugged. Upon re-starting the pump at 6:18 pm, the pump produced a steady flow rate of 270 gpm, but the power was accidentally disconnected at 6:26 pm. The well was allowed to recover, and the pump was re-started for a final time at 6:51 pm.

Figure A-8. AS&G Well Pump Test Summary



Water level data during the drawdown cycle of the AS&G Well pumping test are shown on Figure A-9. A semilogarithmic plot is often used for drawdown analysis, during which water levels at later times should approach a straight line with a positive slope (i.e., drawdown should increase with time). In contrast, water levels during pumping

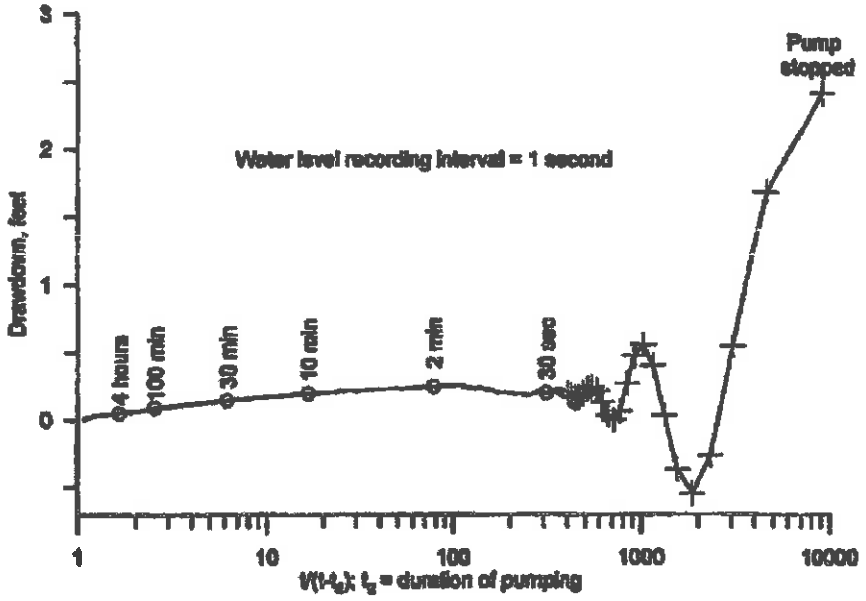
Figure A-9. Drawdown Data – AS&G Well Pumping Test



showed decreasing drawdowns after the first 6 seconds of pumping. One explanation for this behavior is that the pump used during the test may be more powerful than previous pump(s) installed in this well. This would tend to remove fine sediment from the well screen and surrounding formation, thereby increasing the hydraulic conductivity in the vicinity of the well. Because of the decrease in drawdown over time, the drawdown data were not used for to determine hydraulic conductivity.

Water level data during the recovery period following the pump test are shown on Figure A-10. Recovery data are analyzed using a semilogarithmic plot of drawdown versus the quantity $t/(t-t_2)$, where t is the time since pumping started and t_2 is the duration of pumping. The recovery data show a series of oscillations after the pump was shut off, followed by a gradual water level recovery. Oscillating recoveries are commonly observed during slug tests in high-permeability aquifers (van der Kamp 1976), and are attributed to inertial forces within the well casing. In contrast, the aquifer response away from the well casing is best respresented by intermediate- and late-time recovery data, after the oscillations have ceased.

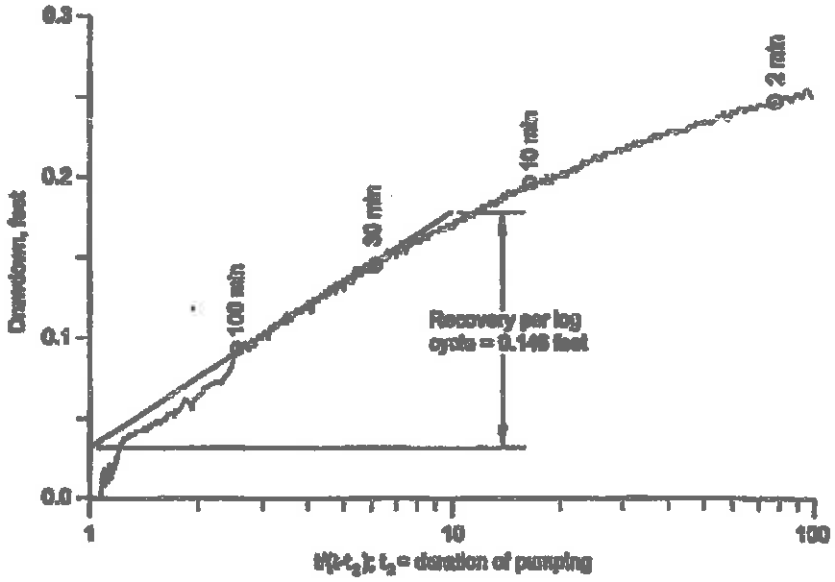
Figure A-10. Summary of AS&G Well Recovery Data



When plotted against $t/(t-t_2)$ on semilogarithmic axes, the recovery data should approximate a straight line at intermediate and late times. As shown on Figure A-11, the largest rate of recovery occurred between 90 and 100 minutes after pumping stopped, indicating an hydraulic conductivity of about 1,400 feet per day. The

somewhat erratic data collected after 100 minutes appears to have been affected by retrieval and replacement of the transducer (at 11:05 pm), and by rising water levels over the course of the next day (up to 0.03 feet). These effects can be minimized by limiting the analysis to the period between 30 and 100 minutes after the cessation of pumping.

Figure A-11. Curve Fit of AS&G Well Recovery Data



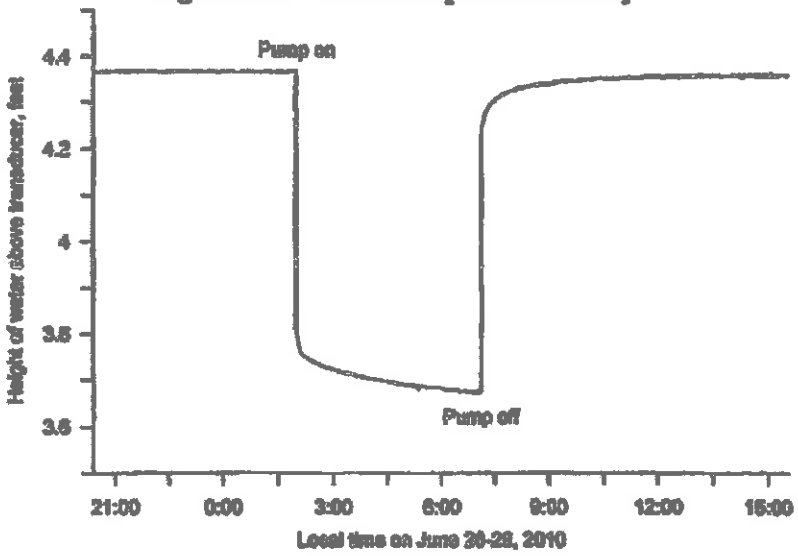
A3 June 2010 Pumping Test on Well I

Although the water table is relatively flat on the north half of AS&G's property (Figure 2-5), the slope of the water table increases to the southwest. To investigate the hydraulic conductivity in this area, a pumping test was performed on Well I. This well is equipped with a pump, and provides domestic water for the break shack adjacent to AS&G's equipment maintenance shop. A well log is not available for Well I, but it is 57 feet deep, with a static water level about 34 feet below ground surface. The well is 6 inches in diameter, and probably consists of open-ended steel casing. Based on Figure 3-1, the depth to bedrock at Well I is about 105 feet.

The pump discharge from Well I passes through about 40 feet of buried ¾-inch copper pipe before entering a pressure tank in the break shack. To maximize the flow rate, temporary piping was installed to bypass the pressure tank, discharging to the ground surface about 70 feet northeast of the well. From there the discharge flowed northeast into a vegetated area.

To check for natural water level fluctuations, water levels in Well I were recorded for about 8 hours before the test. The well was pumped at 7.2 gpm for 5 hours, and the recovery of water levels was recorded for 9 hours after the test. Unlike the AS&G Well test, drawdown increased throughout the pumping period (Figure A-12), but the resulting hydraulic conductivity values were lower than those obtained during the recovery period. Because hydraulic conductivity values obtained during pumping can be biased by friction losses, the following analysis focuses on data obtained during the recovery period.

Figure A-12. Well I Pump Test Summary



Water level recovery data following the Well I pumping test are shown on Figure A-13. This plot has the same semilogarithmic axes as those discussed for Figure A-10. Due to the lower permeability at this location, initial recovery data does not exhibit the oscillations typical of high-permeability formations (van der Kamp 1976). Rather, the drawdown data shows a rapid decline after the pump was turned off, followed by a linear water level recovery. The slope of the recovery plot between 30 minutes and 8 hours after the cessation of pumping yields an hydraulic conductivity of 53 feet per day, which is significantly lower than the values measured at Wilder Pond and the AS&G Well. This is consistent with the low yield of Well I (7.2 gpm) as compared with the AS&G Well (270 gpm) and Wilder Pond (3,300 gpm).

ACKNOWLEDGMENTS

This report was prepared by Franklin Associates, a subcontractor of TechLaw, Inc., a prime contractor of the United States Environmental Protection Agency Office of Solid Waste. Eugene Lee served as EPA's work assignment manager. Marjorie A. Franklin was Franklin Associates' Principal-in-charge and Jacob E. Beachey was the project manager and primary author of the report.

We are pleased to acknowledge much valuable support and input from some of the leading research organizations in construction and demolition debris management. Peter Yost, of the NAHB Research Center, participated in all phases of the project, providing input on methodology, data sources, and analysis. Robert Brickner, of Gershman, Brickner and Bratton, Inc., reviewed the entire report and made significant contributions, particularly in the sections on C&D debris from road, bridges, and other non-building activities.

A large number of people, ranging from local governmental agencies to large demolition contractors, provided waste assessment data for this project. These people are identified in the reference sections at the end of the chapters of this report.

We appreciate the efforts of the peer reviewers, who reviewed the report and provided valuable comments and suggestions. The peer reviewers for the report are

CHARACTERIZATION OF BUILDING-RELATED CONSTRUCTION AND DEMOLITION DEBRIS IN THE UNITED STATES

Executive Summary

INTRODUCTION

The purpose of this report is to characterize the quantity and composition of building-related construction and demolition (C&D) debris generated in the United States, and to summarize the waste management practices for this waste stream. C&D debris is produced when new structures are built and when existing structures are renovated or demolished. Structures include all residential and nonresidential buildings as well as public works projects, such as streets and highways, bridges, piers, and dams. Many state definitions of C&D debris also include trees, stumps, earth, and rock from the clearing of construction sites.

The focus of this report is on building-related wastes, including construction, demolition, and renovation of residential and nonresidential buildings. Road and bridge debris, land clearing debris, etc. are not covered in detail in this report. They are, however, discussed briefly.

METHODOLOGY

The methodology used for this study combines national Census Bureau data on construction industry activities with point source waste assessment data (i.e., waste sampling and weighing at a variety of construction and demolition sites) to estimate the amount of building-related C&D debris produced nationally.

It is important to recognize that this is a first attempt to use this methodology. It is expected that as the trend towards better characterization of C&D sites continues and more communities record their C&D debris quantities and compositions, the national estimates as developed in this report can be tested and modified accordingly. Currently, the limited point source waste assessment data may be a source of considerable uncertainty in the analysis.

Since the method developed here makes use of readily available Census Bureau data on national C&D activity, (e.g., construction and demolition permits and construction value) the methodology should be well suited for periodic updating. Waste assessment results should change very slowly over time because construction materials used and building construction practices remain relatively constant from year to year. Composition of waste from demolished buildings, which have been built over a range of years, should change even more slowly.

DEFINITIONS
(For purposes of this report, following is a working set of definitions)

Construction and Demolition (C&D) Debris is waste material that is produced in the process of construction, renovation, or demolition of structures. Structures include buildings of all types (both residential and nonresidential) as well as roads and bridges. Components of C&D debris typically include concrete, asphalt, wood, metals, gypsum wallboard, and roofing. Land clearing debris, such as stumps, rocks, and dirt, are also included in some state definitions of C&D debris.

Generation of C&D debris, as used in this report, refers to the weight of materials and products as they enter the waste management system from the construction, renovation, or demolition of structures, and before materials recovery or combustion takes place. Source reduction activities (e.g., on-site usage of waste wood mulch or the on-site use of drywall as a soil amendment) take place *ahead* of generation, i.e., they reduce the amount of waste generated.

Recovery of materials, as estimated in this report, includes the removal of products or materials from the waste stream for the purpose of **recycling** the materials in the manufacture of new products.

Source reduction activities reduce the amount or toxicity of wastes before they enter the waste management system. **Reuse** is a source reduction activity involving the recovery or reapplication of a product or material in a manner that retains its original form and identity. Reuse of products such as light fixtures, doors, or used brick is considered source reduction, not recycling.

Discards include the C&D debris remaining after recovery for recycling (including composting). These discards would presumably be combusted or landfilled, although some debris is littered, stored or disposed on-site, or burned on-site.

REPORT HIGHLIGHTS

Building-Related C&D Debris Generation Estimates

- An estimated 136 million tons of building-related C&D debris were generated in 1996 (Table ES-1).
- The estimated per capita generation rate in 1996 was 2.8 pounds per person per day.
- Forty-three percent of the waste (58 million tons per year) is generated from residential sources and 57 percent (78 million tons per year) is from nonresidential sources.
- Building demolitions account for 48 percent of the waste stream, or 65 million tons per year; renovations account for 44 percent, or 60 million tons per year; and 8 percent, or 11 million tons per year, is generated at construction sites.

Table ES-1

SUMMARY OF ESTIMATED BUILDING-RELATED C&D DEBRIS GENERATION, 1996*
(Roadway, Bridge, and Land Clearing Debris not included)
(Thousand Tons)

Source	Residential		Nonresidential		Totals	
	Thou tons	Percent	Thou tons	Percent	Thou tons	Percent
Construction	6,560	11	4,270	6	10,830	8
Renovation	31,900	55	28,000	36	59,900	44
Demolition	19,700	34	45,100	58	64,800	48
Totals	58,160	100	77,370	100	135,530	100
Percent	43		57		100	

* C&D debris managed on-site should, in theory, be deducted from generation. Quantities managed on-site are unknown.

Source: Franklin Associates

Composition of C&D Debris from Buildings

The composition of C&D debris is highly variable and depends critically on the type of activity where sampling is done. Whereas wood is typically the largest component of waste material generated at construction and renovation sites, concrete is commonly the largest component of building demolition debris.

Road, Bridge, and Land Clearing Debris

Road, bridge, and land clearing wastes represent a major portion of total C&D debris, and some of the materials produced are managed by the same processors and landfills that manage building-related wastes. A methodology was not developed in the scope of this project to estimate these wastes. Point source waste assessment data were not available for these projects.

Management Practices for C&D Debris

- The most common management practice for C&D debris is landfilling, including C&D landfills, MSW landfills, and unpermitted sites. An estimated 35 to 45 percent was discarded in C&D landfills in 1996. An estimated 30 to 40 percent of C&D debris is managed on-site, at MSW landfills, or at unpermitted landfills.

- A 1994 survey done for the EPA identified about 1,900 active C&D landfills in the United States.

- An estimated 20 - 30 percent of building-related C&D debris was recovered for processing and recycling in 1996. The materials most frequently recovered and recycled are concrete, asphalt, metals, and wood.

- There is an trend toward increasing recovery of C&D debris in the United States. ***C&D Recycling*** estimates there are about 3,500 operating facilities that process C&D debris materials in the United States.

- Recent deconstruction demonstration projects show that high diversion rates may be achieved. Deconstruction minimizes contamination of demolition debris; however, it is labor intensive, and generally requires more time than traditional demolition.

- Metals have the highest recycling rates among the materials recovered from C&D sites. The Steel Recycling Institute estimates that the recycling rate for C&D steel is about 85 percent (18.2 million tons out of 21.4 million tons generated). These numbers include not only scrap steel from buildings but also from roads and bridges.

- We estimate there are about 500 wood processing facilities in the United States that derive wood from C&D debris. The leading states for these wood processing plants are North Carolina, Oregon, and California.

Peer Review and Data Sources

This first edition report underwent extensive internal and external peer review of methodology and data sources. Major contributors of data sources and peer review include the National Association of Home Builders Research Center; Gershman, Brickner & Bratton, Inc.; EPA Region 5, and the U.S. Department of Commerce, Bureau of the Census.

As part of an ongoing effort to better characterize non-hazardous wastes subject to regulation under Subtitle D of RCRA, USEPA encourages public comment on this report, including additional methodological considerations and data sources.

Chapter 1

INTRODUCTION AND METHODOLOGY

BACKGROUND

The purpose of this report is to characterize building-related construction and demolition (C&D) debris generated in the United States. Construction and demolition debris is produced when new structures are built and when existing structures are renovated or demolished. Structures include all residential and nonresidential buildings as well as public works projects, such as streets and highways, bridges, piers, and dams. Many state definitions of C&D debris also include trees, stumps, earth, and rock from the clearing of construction sites.

National estimates of construction and demolition debris generation have been limited in the past to extrapolation of local data, using population or construction employment to make the extrapolations. Values for generation rates reported in various locations across the country have ranged from 0.12 to 3.52 pounds per capita per day (Wilson 1977), a range too large for meaningful extrapolations.

At least three studies in the past 30 years have made national generation rate estimates. The first was a 1969 Public Health Service study, which reported a national average of 0.66 pounds per person per day (ppd) (PHS 1969). The same study reported an urban average generation rate of 0.72 ppd, a number which was also reported in the 1986 EPA municipal solid waste characterization report as an estimate for the national average (EPA 1986). Based on the U.S. population in 1986 (240 million), the EPA report estimated 31.5 million tons per year of C&D debris generation.

In a draft report prepared for the National Renewable Energy Laboratory in 1994 (Franklin 1994), Franklin Associates identified 22 cities, counties, or states for which C&D debris data were reported. There was a weak but positive correlation between C&D debris generation and per capita construction employment in each area. The national extrapolated estimate for C&D debris generation using that methodology was 64.4 million tons per year.

The previous C&D debris estimates for the United States now appear to be low, based on the results of this study. As discussed in the sections that follow, we estimate that C&D debris generation for building-related wastes only (i.e., excluding wastes from roadways, bridges, land clearing, and excavation), was about 136 million tons in 1996.

METHODOLOGY

The initial objective of this study was to develop a methodology somewhat parallel to EPA's material flows methodology used for MSW characterization that would use readily available national data, which would be suitable for periodic updates. The material flows methodology starts with national production data by material and product, adjusts for imports, exports, average lifetimes, and consumption, and then calculates national generation by summing up all the materials and products that make up MSW. Because of the long and extremely variable lifetimes of buildings, roads, and other structures, the material flows method was determined to be infeasible for C&D debris.

Another approach—sampling and weighing at landfills—is often used for determining local waste management system needs and would be the preferred method for this study if sufficient time and funds were available. However, even on the local level there may be significant barriers to this method. Sampling from a mixed waste stream with statistical confidence is very difficult, time consuming, and costly. Locating all the places where C&D debris is placed is not a trivial matter in some localities, and obtaining permission to sample at private landfills can be a major challenge. For a national study of this type, this method would be both cost and time prohibitive.

The methodology used for this study combines national Census Bureau data on construction industry project activity with point source waste assessment data (i.e., waste sampling and weighing at a variety of construction and demolition sites) to estimate the amount of C&D debris produced nationally. Because of the lack of point source waste assessment data from roadway, bridge, and landclearing projects, this study was limited to building-related wastes.

It is important to recognize that this is a first attempt to use this methodology. We expect that as the trend towards better characterization of C&D sites continues where more communities record their C&D debris quantities and compositions, the national estimates as developed in this report can be tested and modified accordingly. Currently, the limited point source waste assessment data may be a source of considerable uncertainty in the analysis.

Since the methodology developed here makes use of readily available Census Bureau data on national C&D activity, (e.g., construction and demolition permits and construction value) the methodology should be well suited for periodic updating. Waste assessment results should change very slowly over time because construction materials used and building construction practices remain relatively constant from year to year. Composition of waste from demolished buildings, which were built over a range of years, should change even more slowly.

PEER REVIEW AND DATA SOURCES

This first edition report underwent extensive internal and external peer review of methodology and data sources. Major contributors of data sources and peer review include the National Association of Home Builders Research Center, Gershman, Brickner & Bratton, Inc., EPA Region 5, and the U.S. Department of Commerce, Bureau of the Census.

During the peer review process, a consensus was reached that this report represents a credible attempt at estimating national generation of building-related construction and demolition debris. However, the report could benefit from additional waste sampling studies to strengthen the source category (construction, demolition, and renovation) estimates. Further, future editions will need to address roadway, bridge, and land clearing debris in order to present a more complete picture of the national construction and demolition waste stream. As part of an ongoing effort to better characterize non-hazardous wastes subject to regulation under Subtitle D of RCRA, USEPA encourages public comment on this report, including additional methodological considerations and data sources.

DEFINING C&D DEBRIS

A broad definition of the representative projects and sources of C&D debris is shown below (Table 1). This table shows that the generation sources of C&D debris cover a broad segment of the U.S. economy. The sources range from homebuilders and homeowners to general commercial developers, general building contractors, highway and street contractors, bridge erectors/constructors, bituminous pavement contractors, small home remodelers, site grading contractors, demolition contractors, roofing contractors and drywallers, and excavation specialists.

The amount of C&D debris generated and reported to regulatory agencies around the country varies considerably from one community to another. This variation is created, in part, by the difference in state regulations on the subject material, and also by the historical demographics and current growth and development activity of the community.

Excerpts from a number of state definitions of C&D debris are presented in this chapter, with more complete citations in Appendix B. This is a representative sample of how states are defining C&D debris. It illustrates the diversity of C&D debris terminology. Several states include land-clearing debris as C&D; however, Massachusetts, New York, and North Carolina specifically exclude these materials. Oregon excludes clean fill materials when separated from other C&D wastes and used as fill materials or otherwise land disposed. New York, Kansas, and Rhode Island's definitions specifically exclude some materials, even

Table 1

REPRESENTATIVE GENERATION SOURCES OF C&D SECTOR MATERIALS*

Site clearance materials
(Brush, tree, and stumpage materials)

Excavated materials
(Earth, fill, and other excavated rock and granular materials)

Roadwork materials
Concrete slabs and chunks from concrete road construction
Asphalt chunks and millings from asphalt pavement
Bridge/overpass construction/renovation materials

New construction materials
(Residential, commercial, and industrial project sources)

Renovation, remodeling or repair materials
(Residential, commercial, and industrial project sources)

Demolition materials . . . including wrecking, implosion, dismantling, and deconstruction
(Residential, commercial, and industrial project sources)

Disaster debris

* Note that estimates for site clearance, excavated materials, and roadwork materials are not included in this report.

Source: Gershman, Brickner & Bratton, Inc. Fairfax, Virginia

if resulting from C&D activities. Examples of exclusions include garbage, carpeting, furniture, corrugated containerboard, and other containers.

The variance in state definitions affects the interpretation of the results of this report. Corrections or adjustments may be required when comparing the results of this report with state data, depending on the definition the state used. Corrections may also be required when comparing data from any two states.

The amount of C&D debris available for discard in any region also depends on the general economic conditions of the region, the weather, major disasters, special projects, and local regulations. In fast growing areas, the C&D waste stream from buildings consists primarily of construction debris, with much smaller quantities of demolition debris. Demolition debris is produced when older buildings are demolished to make way for the new developments. By contrast, in many urban areas demolition debris dominates the C&D waste stream.

STATE DEFINITIONS FOR CONSTRUCTION AND DEMOLITION DEBRIS
(A representative sample of definitions that points out the variability of definitions used)

California. Construction and demolition (C&D) debris includes concrete, asphalt, wood, drywall, metals, and many miscellaneous and composite materials. C&D debris is generated by demolition and new construction of structures such as residential and commercial buildings and roadways.

Florida. "Construction and demolition debris" means discarded materials generally considered to be not water soluble and non-hazardous in nature, including but not limited to steel, glass, brick, concrete, asphalt material, pipe, gypsum wallboard, and lumber, from the construction or destruction of a structure as part of a construction or demolition project or from the renovation of a structure, including such debris from construction of structures at a site remote from the construction or demolition project site. The term includes rocks, soils, tree remains, trees, and other vegetative matter which normally results from land clearing or land development operations for a construction project; clean cardboard, paper, plastic, wood and metal scraps from a construction project . . . unpainted, non-treated wood scraps from facilities manufacturing materials used for construction of structures or their components and unpainted, non-treated wood pallets provided the wood scraps and pallets are separated from other solid waste; and the commingling of wood scraps or pallets with other solid waste; and *de minimis* amounts of other non-hazardous wastes that are generated at construction or demolition projects . . . .

Hawaii. "Construction and demolition waste" means solid waste, largely inert waste, resulting from the demolition or razing of buildings, of roads, or other structures, such as concrete, rock, brick, bituminous concrete, wood, and masonry, composition roofing and roofing paper, steel, plaster, and minor amounts of other metals, such as copper. Construction and demolition waste does not include cleanup materials contaminated with hazardous substances, friable asbestos, waste paints, solvents, sealers, adhesives, or similar materials.

Kansas. "Construction and demolition waste" means solid waste resulting from the construction, remodeling, repair and demolition of structures, roads, sidewalks and utilities; and solid waste consisting of vegetation from land clearing and grubbing, utility maintenance, and seasonal or storm-related cleanup. Such wastes include, but are not limited to, bricks, concrete and other masonry materials, roofing materials, soil, rock, wood, wood products, wall covering, plaster, drywall, plumbing fixtures, electrical wiring, electrical components containing no hazardous materials and non asbestos insulation. It shall not include asbestos waste, garbage, cardboard, furniture, appliances, electrical equipment containing hazardous materials, tires, drums and containers even though such wastes resulted from construction and demolition activities. Clean rubble that is mixed with other construction and demolition waste during demolition or transportation shall be considered to be construction and demolition waste.

Kentucky. . . . Construction/demolition debris . . . results from the construction, remodeling, repair, and demolition of structures and roads and . . . uncontaminated solid waste consisting of vegetation resulting from land clearing and grubbing, utility line maintenance, and seasonal and storm-related cleanup. Such waste includes, but is not limited to bricks, shredded or segmented tires, concrete and other masonry materials, soil, rock, wood, wall coverings, plaster, drywall, plumbing fixtures, tree stumps, limbs, saw dust, leaves, yard waste, paper, paper products, metals, furniture, insulation, roofing shingles, asphalt pavement, glass, plastics that are not sealed in a manner that conceals other wastes, electrical wiring and components containing no liquids or hazardous metals that are incidental to any of the above . . . . Asbestos . . . only if approved by the division . . . .

STATE DEFINITIONS FOR CONSTRUCTION AND DEMOLITION DEBRIS (Continued)

Maricopa County, Arizona. Construction debris is a general term used to describe a large class of solid wastes usually generated as a byproduct of the construction, demolition, or maintenance of residences, commercial or industrial facilities and infrastructure. Construction debris includes such materials as: broken concrete, asphalt, steel, aluminum, glass, brick, tile, paper, plastics, wood products, sheet rock, street sweepings and canal dredgings.

Massachusetts. C&D waste is comprised of debris generated from construction, renovation, repair, and demolition of roads, bridges, and buildings and includes wood, steel, concrete, masonry, plaster, metal, and asphalt, but not wood from land-clearing, i.e. stumps, logs, brush, and soil, nor rock from excavations.

Minnesota. Construction Wastes—Building materials, packaging, and rubble resulting from construction, remodeling, repair, and demolition of buildings and roads.
Demolition Debris—Solid waste resulting from the demolition of buildings, roads, and other man-made structures, including concrete, brick, bituminous concrete, untreated wood, masonry, glass, trees, rock, and plastic building parts. Demolition debris does not include asbestos.

North Carolina. "Construction" or "demolition" when used in connection with "waste" or "debris" means solid waste resulting solely from construction, remodeling, repair, or demolition operations on pavement, buildings, or other structures, but does not include inert debris, land-clearing debris or yard debris.

Nebraska. "Construction and demolition waste" shall mean waste which typically results from construction or demolition projects and includes all materials which are the by-products of construction work or which result from demolition of buildings and other structures, including, but not limited to brick, concrete rubble, masonry materials, paper, gypsum board, wood, rubber and plastics. Construction and demolition waste does not include friable asbestos-containing materials, liquid waste, hazardous waste, putrescible waste or furnishings from demolished structures.

New York. Construction and demolition (C&D) debris means uncontaminated solid waste resulting from the construction, remodeling, repair and demolition of utilities, structures and roads; and uncontaminated solid waste resulting from land clearing. Such waste includes, but is not limited to bricks, concrete and other masonry materials, soil, rock, wood (including painted, treated and coated wood and wood products), land clearing debris, wall coverings, plaster, drywall, plumbing fixtures, non asbestos insulation, roofing shingles and other roof coverings, asphalt pavement, glass, plastics that are not sealed in a manner that conceals other wastes, empty buckets ten gallons or less in size and having no more than one inch of residue remaining on the bottom, electrical wiring and components containing no hazardous liquids, and pipe and metals that are incidental to any of the above. Solid waste that is not C&D debris (even if resulting from the construction, remodeling, repair and demolition of utilities, structures and roads and land clearing) includes, but is not limited to asbestos waste, garbage, corrugated container board, electrical fixtures containing hazardous liquids such as fluorescent light ballasts or transformers, fluorescent lights, carpeting, furniture, appliances, tires, drums, containers greater than ten gallons in size, any containers having more than one inch of residue remaining on the bottom and fuel tanks. . . .

STATE DEFINITIONS FOR CONSTRUCTION AND DEMOLITION DEBRIS (Continued)

Oregon. "Construction and Demolition Waste" means solid waste resulting from the construction, repair or demolition of buildings, roads and other structures, and debris from the clearing of land, but does not include clean fill when separated from other construction and demolition wastes and used as fill materials or otherwise land disposed. Such waste typically consists of materials including concrete, bricks, bituminous concrete, asphalt paving, untreated or chemically treated wood, glass, masonry, roofing, siding, plaster; and soils, rock, stumps, boulders, brush and other similar material. This term does not include industrial solid waste and municipal solid waste generated in residential or commercial activities associated with construction and demolition activities.

Portland, Oregon Metropolitan Service District. Construction Waste - Waste materials resulting from the construction, remodeling and repair of buildings and other structures.
Demolition Waste - Solid waste, largely inert, resulting from the demolition or razing of buildings, roads, and other man-made structures. Demolition waste consists of, but is not limited to, concrete, brick, bituminous concrete, wood, masonry, composition, roofing and roofing paper, steel, and amounts of other metals like copper. Plaster (i.e., sheet rock or plasterboard), any other non-wood material that is likely to produce gases or leachate during the decomposition proces" and asbestos wastes are not considered to be demolition wastes.

Rhode Island. "Construction and Demolition (C&D) Debris" shall mean non-hazardous solid waste resulting from the construction, remodeling, repair, and demolition of utilities and structures; and uncontaminated solid waste resulting from land clearing. Such waste includes, but is not limited to wood (including painted, treated and coated wood and wood products), land clearing debris, wall coverings, plaster, drywall, plumbing fixtures, non-asbestos insulation, roofing shingles and other roofing coverings, glass, plastics that are not sealed in a manner that conceals other wastes, empty buckets ten gallons or less in size and having no more than one inch of residue remaining on the bottom, electrical wiring and components containing no hazardous liquids, and pipe and metals that are incidental to any of the above. Solid waste that is not C&D debris (even if resulting from the construction, remodeling, repair, and demolition of utilities, structures, and roads and land clearing) includes, but is not limited to, asbestos waste, garbage, corrugated container board, electrical fixtures containing hazardous liquids such as fluorescent light ballasts or transformers, fluorescent lights, carpeting, furniture, appliances, tires, drums, containers greater than ten gallons in size, any containers having more than one inch of residue remaining on the bottom, and fuel tanks. . . .

South Carolina. "Construction and demolition debris" means discarded solid wastes resulting from construction, remodeling, repair and demolition of structures, road building, and land-clearing. The wastes include, but are not limited to, bricks, concrete, and other masonry materials, soil, rock, lumber, road spoils, paving material, and tree and brush stumps, but does not include solid waste from agricultural or silvicultural operations.

Washington. "Demolition waste" means solid waste, largely inert waste, resulting from the demolition or razing of buildings, roads and other man-made structures. Demolition waste consists of, but is not limited to, concrete, brick, bituminous concrete, wood and masonry, composition roofing and roofing paper, steel, and minor amounts of other metals like copper. Plaster (i.e., sheet rock or plaster board) or any other material, other than wood, that is likely to produce gases or a leachate during the decomposition process and asbestos wastes are not considered to be demolition waste . . . .

See Appendix B for complete texts and citations.

The components that make up C&D debris also vary a great deal depending on the type of construction and the methods used by the construction industry. Table 2 shows typical contents of C&D debris by broad material types. Table C-1 in Appendix C shows a more detailed list of C&D debris components.

Construction debris from building sites typically consists of trim scraps of construction materials, such as wood, sheetrock, masonry, and roofing materials. There is typically much less concrete in construction debris than demolition debris, although some construction projects produce considerable quantities of concrete, depending on the technology used to build the concrete walls. Scrap from residential construction sites typically represents between 6 and 8 percent of the total weight of the building materials delivered to the site, excluding the foundation, concrete floors, driveways, patios, etc. There is typically very little waste concrete to dispose of from residential construction projects.

Table 2

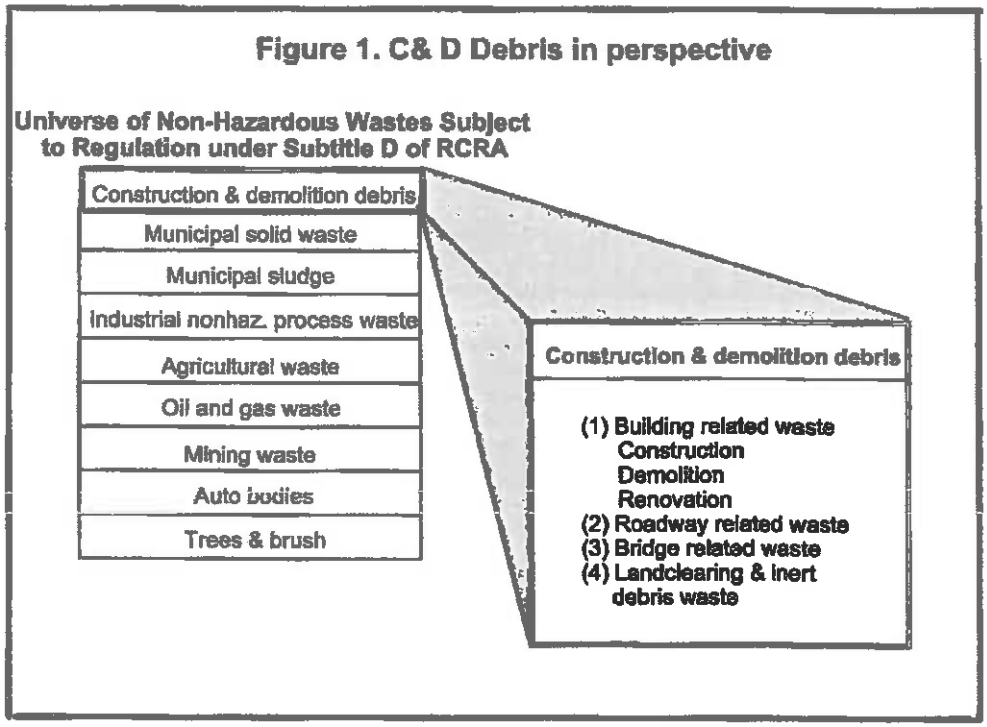
TYPICAL COMPONENTS OF CONSTRUCTION AND DEMOLITION DEBRIS

Material Components	Content Examples
Wood	Forming and framing lumber, stumps, plywood, laminates, scraps
Drywall	Sheetrock, gypsum, plaster
Metals	Pipes, rebar, flashing, steel, aluminum, copper, brass, stainless steel
Plastics	Vinyl siding, doors, windows, floor tile, pipes
Roofing	Asphalt & wood shingles, slate, tile, roofing felt
Rubble	Asphalt, concrete, cinder blocks, rock, earth
Brick	Bricks and decorative blocks
Glass	Windows, mirrors, lights
Miscellaneous	Carpeting, fixtures, insulation, ceramic tile

When buildings are demolished, large quantities of waste may be produced in a relatively short period of time, depending on the demolition technique used. The demolition project duration can vary depending on the technique used—implode a structure with explosives, use a crane and wrecking ball technique, or deconstruct the structure. In actual practice, the vast majority of demolition projects use a combination of the last two basic techniques depending on the materials used in the original project, the physical size of the structure, the surrounding buildings that cannot be disturbed or impacted, and the time allocated for the project. One hundred percent of the weight of a building, including the concrete foundations, driveways, patios, etc., may be generated as C&D debris when a building is demolished. On a per building basis, demolition waste quantities may be 20 to 30 times as much as construction debris.

CONSTRUCTION AND DEMOLITION DEBRIS IN PERSPECTIVE

C&D debris is generally a non-hazardous waste subject to regulation under Subtitle D, as shown in Figure 1. Other non-hazardous wastes include municipal solid waste (MSW), sludges from water and wastewater treatment plants, nonhazardous wastes from industrial processes, agricultural wastes, oil and gas wastes, mining wastes, spent automobiles, and trees and brush. MSW, which is primarily the waste from residential and commercial sources, has been characterized in more detail and for a longer period of time by the EPA than the other non-hazardous wastes. A material flows methodology was developed for MSW characterization in the late 1960s and early 1970s, and has been modified and updated periodically since then. The latest of the EPA reports was published in May of 1998 (EPA 1998).



Although the C&D debris stream is usually described based on its origin as outlined in Table 1 above, there are some potential overlaps with other waste streams, in particular, MSW. For example, the MSW characterization includes all postconsumer corrugated boxes, even though significant quantities of these boxes enter the waste stream from building construction sites. (See Appendix A, Table A-11.) To simply sum up the national quantities of MSW and C&D debris could result in double counting. Other examples of MSW sometimes collected at C&D sites include wood pallets, food and beverage containers, caulking tubes, and paint containers. On the other hand, building material wastes are frequently collected by MSW waste management systems. However, EPA's material flows

methodology does not include them. Examples include pipes, plumbing fixtures, and building materials that are replaced by residents and discarded with their household trash. The overlap issues are discussed further in Chapter 4 of this report.

The six activities that generate C&D debris from buildings include the construction, demolition, and renovation (improvements and repair) of both residential and nonresidential buildings. Residential buildings include single-family houses and duplexes, up to and including high rise multi-family housing. Nonresidential buildings include commercial, institutional, and industrial buildings.

Construction activities generally produce cleaner materials than demolition. Demolitions may produce several types of materials bonded together or contaminated with hazardous materials, such as asbestos or lead paint. Renovation projects can produce both construction and demolition type wastes.

DEFINITIONS
(For purposes of this report, following is a working set of definitions)

Construction and Demolition (C&D) Debris is waste material that is produced in the process of construction, renovation, or demolition of structures. Structures include buildings of all types (both residential and nonresidential) as well as roads and bridges. Components of C&D debris typically include concrete, asphalt, wood, metals, gypsum wallboard, floor tile, and roofing. Land clearing debris, such as stumps, rocks, and dirt, are also included in some state definitions of C&D debris.

Generation of C&D debris, as used in this report, refers to the weight of materials and products as they enter the waste management system from the construction, renovation, or demolition of structures, and before materials recovery or combustion takes place. Source reduction activities (e.g., on-site usage of waste wood mulch or the on-site use of drywall as a soil amendment) take place *ahead* of generation, i.e., they reduce the amount of waste generated.

Recovery of materials, as estimated in this report, includes the removal of products or materials from the waste stream for the purpose of recycling the materials in the manufacture of new products.

Source reduction activities reduce the amount or toxicity of wastes before they enter the waste management system. **Reuse** is a source reduction activity involving the recovery or reapplication of a product or material in a manner that retains its original form and identity. Reuse of products such as light fixtures, doors, or used brick is considered source reduction, not recycling.

Discards include the C&D debris remaining after recovery for recycling (including composting). These discards would presumably be combusted or landfilled, although some debris is littered, stored or disposed on-site, or burned on-site.

OVERVIEW OF THIS REPORT

Chapter 1 contains background information on the methodology used for this report, examples of state definitions for C&D debris, and perspectives on the components of C&D and its relationship to other non-hazardous wastes. Chapter 2 contains estimates of the national generation of the building fraction of C&D debris from each of six major building C&D activities, i.e., residential construction, demolition, and renovation, and nonresidential construction, demolition, and renovation. Examples of locally generated data for the other C&D related generating sectors, e.g., roadway, bridge, and land clearing debris are presented for illustrative purposes. Also included in Chapter 2 are some data showing the composition of C&D debris from the various C&D activities.

Chapter 3 of the report discusses the options for management of C&D debris in the United States, including landfilling and recovery for recycling.

Chapter 4, Perspectives, discusses the overlap of the C&D debris waste stream and the MSW waste stream.

Chapter 2

GENERATION OF CONSTRUCTION AND DEMOLITION DEBRIS

INTRODUCTION

For the purposes of this initial national report, emphasis has been placed on the generation of construction and demolition (C&D) debris from building construction, demolition, and renovation activities. Examples of locally generated data for the other C&D-related generating sectors, e.g., roadway, bridge, and land clearing debris, are presented.

BUILDING-RELATED CONSTRUCTION AND DEMOLITION DEBRIS GENERATION

For analysis purposes, building C&D debris is divided into six categories: residential construction, demolition, and renovation and nonresidential construction, demolition, and renovation. These categories were selected based on the relationship between available Census data and empirical composition factors.

The following sections describe the data used and the methods for estimating the amount of building-related C&D debris generated, on a weight basis. Tables A-1 through A-6 in Appendix A are worksheets that provide details of the calculations used to arrive at generation for each component of the C&D debris stream.

Construction Debris

Residential. Empirical data for new residential construction have been identified from five sources: The NAHB Research Center; METRO in Portland, Oregon; Woodbin 2 in Cary, North Carolina; McHenry County, Illinois; and Cornell University. Each of these groups has conducted waste assessments at new construction sites.

The National Association of Homebuilders (NAHB) Research Center has developed a detailed methodology for conducting waste assessments at construction sites. Assessment data have been analyzed for single-family residential construction debris at four sites, including Largo, Maryland; Anne Arundel County, Maryland; Portland, Oregon; and Grand Rapids, Michigan. The NAHB Research Center also conducted a waste assessment at a 36-unit condominium construction project in Odenton, Maryland.

The Metropolitan Service District in Portland, Oregon (METRO) conducted a series of sampling projects at a large number of residential construction sites in Oregon over the last 5 or more years.

Wake County, North Carolina and the North Carolina Division of Pollution Prevention and Environmental Assistance conducted five residential construction waste assessments in the Raleigh, North Carolina area. Woodbin 2, a non-profit organization of the County, organized the assessments.

McHenry County, Illinois conducted waste audits at a single-family construction site and a 6-unit apartment building, and Cornell University conducted a waste audit at a single-family residence in New York.

The data from the five sources are summarized in Table 3. A total of 93 dwelling units are represented on this table. Generation rates ranged from 2.41 to 11.3 pounds per square foot of floor space. Geography does not appear to be the reason for the spread in data; it is more likely the types of houses, the specific practices of the builders, and the lack of uniform standards for the collection and storage of the sampled materials. The weighted average value from the five sources is 4.38 pounds per square foot.

Extrapolation factors are Census Bureau data that record the number of construction permits and the total square feet of new construction. According to the Department of Commerce Current Construction Reports (C-30), in 1996 the value of new private and public residential construction put in place totaled $181.795 billion. Data from areas where permits are required were used to calculate an average dollars per square foot. Total value in areas where permits are required was $127.9 billion for a total of 2,172 million square feet of floor space (1995). This amounts to $58.89 per square foot. Applying this factor to the total C-30 value and correcting 3 percent for inflation results in a total of 2,997 million square feet of new residential construction in 1996. At 4.38 pounds per square foot (Table 3), total generation is **6.56** million tons per year.

Nonresidential. The methodology for nonresidential construction debris is similar to that for residential construction debris. However, nonresidential buildings are much more varied than residential buildings and fewer waste assessments have been done, making the quantity estimates more uncertain.

Nonresidential buildings include private industrial, office, hotels/motels, other commercial, religious, educational, hospital and institutional, and miscellaneous buildings plus public industrial, educational, hospital, and other categories.

Table 4 shows the results of six nonresidential waste assessments. Ranging from 1.61 to 4.21 pounds per square foot, the average generation rate of the individual sampling studies is 3.89 pounds per square foot. These buildings include a retail store, restaurant, institutional building, and two office buildings.

Value of new private and public construction put in place (2)	198,700	million dollars
Average cost of construction (3)	$90.40	per square foot
Total square feet of new construction	2,198	million square feet
Average C&D debris generation rate	3.89	pounds per square foot
Total Generation of Nonresidential Construction Debris	4.27	million tons

(1) Two office buildings.
(2) Department of Commerce Current Construction Reports.
(3) Based on 1995 construction permits, with 3% adjustment to 1996 for inflation.

Source: Franklin Associates

The 1996 value of nonresidential buildings, as reported in Current Construction Reports, is $198.7 billion. Average construction costs in 1995 were $87.77 per square foot, resulting in an estimated 2,197.7 million square feet of new construction, after making a 3 percent correction for inflation. Multiplying by 3.89 pounds per square foot results in a total estimated generation of 4.27 million tons per year.

Demolition Debris

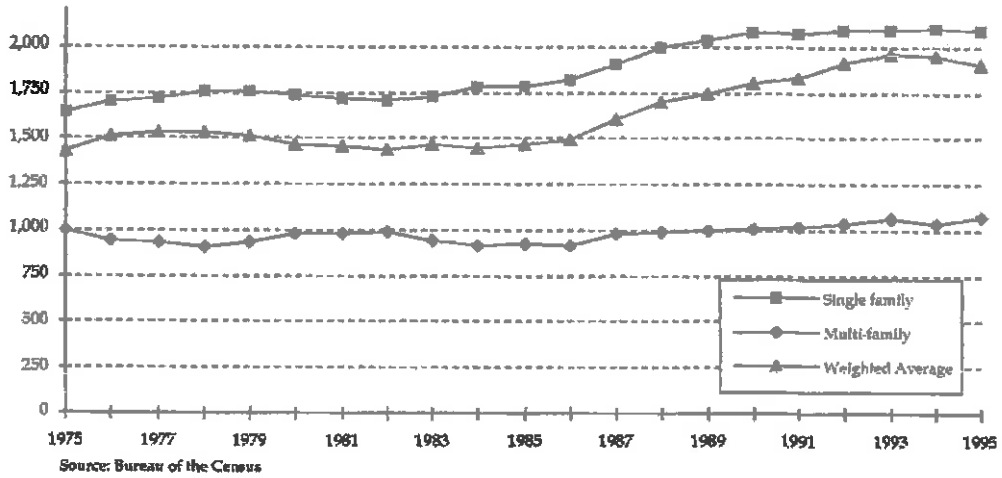
Residential. Demolition debris is estimated, starting with the number of residential demolitions per year, estimating the average house size when demolished, and then multiplying by the waste material per square foot, from empirical demolition waste assessments.

The NAHB economists have estimated the number of demolitions per year, based on Component of Inventory Change (CINCH) data (Carliner 1996). They estimate that the units actually destroyed through intentional demolitions or disasters such as fires or weather-related incidents between 1980 and 1993 averaged 245,000 per year. This is about three times the number reported by the Census Bureau based on permit data. Reasons for the higher number include unpermitted demolitions, municipalities that do not require permits, and

demolition permits that are handled by municipal offices other than building departments. Although CINCH data have been discontinued in 1995 due to federal budget cuts, these data are expected to be available through the American Housing Survey (AHS).

Houses of all ages and sizes may be demolished, but on average it is recognized that older houses are demolished more frequently, and older houses are on average smaller than new ones. New single-family housing units and multi-family housing units (including apartments and condominiums) built in 1995 averaged 2,100 square feet and 1,050 square feet, respectively. Figure 2 shows how average new house sizes have increased over the last 20 years. Multi-family houses have remained nearly the same, while new single-family houses grew from 1,600 square feet to 2,100 square feet. For this analysis, we assumed the average single-family and multi-family house sizes are 1,600 and 1,000 square feet, respectively, when demolished.

Figure 2. Average size of new house construction



Source: Bureau of the Census

Table 5 shows three single-family house demolition assessments and one multi-family deconstruction assessment. The weight of houses when demolished depends critically on whether the houses have concrete foundations and basement walls or not. The use of masonry in exterior cladding also affects the house weight significantly. None of the three single-family houses in Table 5 had full basements. Therefore, we made adjustments to the sampling data to develop an estimate of residential demolition debris which reflects the likely impact of some of the demolished houses having basements.

Table 5

ESTIMATED GENERATION OF RESIDENTIAL DEMOLITION DEBRIS

EMPIRICAL WASTE ASSESSMENTS

Date	Research Group	Type of data	Location	Building Size (Square feet)	C&D Debris (Pounds)	Generation rate (Lb/sq ft)
1992	METRO	SF Demolition (1)	Portland, OR	1,280	66,000	52
1994	METRO	SF Demolition (2)	Portland, OR	1,200	63,000	53

	Weighted average for single-family and multi-family (Appendix A-3)					**115**

EXTRAPOLATION

Estimated number of residential demolitions per year	245,000
Estimated average size of residences demolished (sq ft)	1,396
Average C&D debris generation rate (pounds per square foot)	115
Total Generation of Residential Demolition Debris (tons/yr)	**19,700,000**

(1) 1920s house. Concrete rubble not included.
(2) Concrete rubble not included.
(3) Small house without basement.
(4) Franklin Associates estimate. See Table A-3 for calculation of amount of concrete, in lb/sq ft. (Assumes a composite house, i.e., partial basement, garage, etc.)

Source: Franklin Associates

The Census Bureau provides data on the types of foundations in existing houses in *Current Housing Reports*. Forty-five percent of single-family houses have basements, 26 percent are on concrete slabs, and the remainder have crawl spaces. Table A-3 in the appendix describes an analysis using these percentages to estimate that on average the amount of concrete in a 1,600 square foot single family house is 61 pounds per square foot. The amount can range from zero for houses without basements, garages, or driveways to more than 150 pounds per square foot.

We estimate the total C&D debris generated when single-family houses are demolished is 111 pounds per square foot. For multi-family housing, NAHB Research Center's value of 127 pounds per square foot (Table 5) was used, resulting in an average for all residences of 115 pounds per square foot. Applying this rate to the 245,000 housing units demolished per year results in a waste generation estimate of 19.7 million tons per year, as shown in Table 5.

Nonresidential. The method used to estimate the generation of nonresidential demolition debris is to first determine the number of demolitions per year, then estimate the average size (in square feet) of buildings being demolished. The number of square feet is then multiplied by the generation per square foot, as determined by empirical waste assessments.

The Census Bureau has, until 1995, monitored the number of demolitions, based on permits issued by permit issuing entities. This data series is now discontinued because of federal budget cuts. In 1995, a total of 43,795 nonresidential demolition permits were issued. That number is used in this study as an estimate for 1996. In 1994 there were 45,061 permits issued, which suggests that using the 1995 number for 1996 is a reasonable estimate. Data were not found indicating that the number of demolitions is actually larger than the permits would indicate. Therefore, no correction was made, as was done for residential demolitions. It is less likely that nonresidential demolitions escape the permitting requirements than residential demolitions, because nonresidential demolition is more closely regulated.

We estimated the average nonresidential building size at 13,300 square feet by the following method. The 1996 ***Statistical Abstract*** characterizes existing commercial buildings by type, including the number of buildings, and total square feet based on the time period (decade) when the buildings were built (EIA 1992). Based on those data, we determined that buildings now standing that were built between 1920 and 1969 average 13,300 square feet per building.

Table 6 shows the results of waste assessments at 23 nonresidential buildings over the last several years. The average generation rate is 155 pounds per square foot. Multiplying by the square feet per building and the total number of demolition permits results in a nonresidential demolition debris generation of **45.1** million tons per year.

Renovation Debris

Renovation (or remodeling) includes improvements and repairs to existing buildings. Renovation debris consists of both construction and demolition materials. Remodeling waste quantities are even more variable than construction or demolition waste. Renovation debris ranges from single materials being generated, such as when driveways or roofs are replaced, to multiple material generation, such as when buildings are modified or enlarged. For this analysis, we made estimates for wastes generated when major improvements are made.

Table 6
ESTIMATED GENERATION OF NONRESIDENTIAL DEMOLITION DEBRIS

EMPIRICAL WASTE ASSESSMENTS

Date	Research Group	Type of Building	Location	Building Size Square feet	Total Waste Tons	Generation rate Lb/sq ft

Source: Franklin Associates

Residential. In 1996, the value of residential improvements and repairs amounted to $114.3 billion (Census 1997). Of this, 68 percent (or $77.7 billion) was for improvements and 32 percent (or $36.6 billion) was for repairs. Improvements are defined by the Census Bureau to include additions, alterations, and major replacements which add to the value or useful life of a property, or adapt a property to a new or different use. Repairs include incidental maintenance and repairs to keep a property in ordinary operating condition (C-Series Reports).

Because of the wide variation in remodeling projects, waste assessments to determine generation per square foot are not very useful for estimating total generation. More important is the amount of material produced per job, e.g., per kitchen addition or bath remodeling or roof replacement. Table 7 shows the results of five waste assessments that have been made at residential sites, showing a wide variation in generation rates on a square foot basis. Remodeling typically generates more waste per square foot than new construction, largely because of the demolition that accompanies remodeling. However, some remodeling jobs, like roof replacement, produce relatively low amounts of material on a square foot basis.

Table 7
EMPIRICAL WASTE ASSESSMENTS FOR RESIDENTIAL RENOVATION DEBRIS

Date	Research Group	Type of data	Location	Size of Project (Sq ft)	Total Waste (Pounds)	Generation rate (Lb/sq ft)	Average generation (Lb/sq ft)

Source: Franklin Associates

We estimated renovation debris generation for this analysis by reviewing the number of major home improvements, then estimating the amount of material produced by each type of improvement. Although all home improvement projects cannot be included in a study of this type, selection of the major projects can be useful for making first estimates.

Appendix A Tables A-7, A-8, A-9, and A-10 show some of the assumptions made and the results of estimating the amount of material produced when driveways are replaced, when asphalt and wood roofs from residences having one to four units per structure are replaced, and when residential heating and cooling equipment is replaced. Based on the assumptions made, replacement of these categories produces 13 million tons of concrete from driveways, 6.4 million tons of asphalt roofs, 1.4 million tons of wood roofing, and 1.6 million tons of heating, ventilating, and air conditioning (HVAC) equipment.

The analysis above assumes that 60 percent of residential driveways are made of concrete and are on average 45 feet long (NAHB 1995). Asphalt driveways are also very common, but replacement generates much less waste than concrete, since asphalt driveways are usually overlaid with new asphalt rather than being replaced.

Approximately 67 percent of residences have asphalt roofs (NAHB 1997a). For this analysis, 25 percent were assumed to have wood roofs. Other residential roofing materials include slate, tile, metal, and concrete. These materials are used much less than asphalt and wood, and generally are used over long periods before being replaced.

The NAHB Research Center has compiled estimates of waste generation rates by type of remodeling projects (Yost 1998). The major waste generation remodeling activities involve kitchens, bathrooms, and room additions. Generation from these job types are shown in Table A-5 in Appendix A.

Annually there are approximately 1.25 million major kitchen remodeling jobs (complete tear-out), with an average generation of 4.5 tons per job, and 1.25 million minor kitchen remodeling jobs (facelift, e.g., cabinet replacement) at 0.75 tons per job. Major bath remodelings (1.2 million per year) produce on average one ton of waste material each, and 1.8 million minor bath remodeling jobs produce on average 0.25 tons of waste each. Room additions, estimated at 1.25 million per year, produce on average 0.75 tons apiece. On this basis, we estimated total residential renovation generation, from the improvement or replacement projects itemized above, to be **31.9** million tons per year.

Nonresidential. Based on Census Bureau data, total dollars spent for nonresidential renovation projects in 1996 was $100.4 billion. We calculated this number by assuming the ratio of residential to nonresidential dollars is the same in 1996 as in 1992. We could not find any information on total renovation dollars for 1996.

Very few waste assessments are available for nonresidential renovation. Therefore, the previous methodology cannot be used to estimate this amount. Lacking specific assessment data, we compared total dollars spent on nonresidential and residential renovation and assumed that the amount of waste generated is proportional to dollars spent in these two sectors. (See Table A-6 for more details of this analysis.)

Based on the assumption that waste generation per dollar is equal to the residential rate, total nonresidential renovation is equal to **28.04** million tons per year, less than residential generation by the ratio of dollars spent.

Summary of Building-Related C&D Generation

Table 8 summarizes the estimates for C&D debris generation from the construction, demolition, and renovation of residential and nonresidential buildings in the United States. The estimated total for 1996 is almost 136 million tons, with 43 percent coming from residential and 57 percent from nonresidential sources. Forty-eight percent of the C&D debris generated is from building demolitions, 44 percent is from renovation, and 8 percent is from building construction.

Figure 3 provides a breakdown, in percent of total, of the six building sectors that generate C&D debris. The largest sector is nonresidential demolition at 33 percent. Residential and nonresidential renovation debris make up 23 and 21 percent, respectively, followed by residential demolition at 15 percent. New construction represents 8 percent of total C&D debris, with residential at 3.4 percent and nonresidential at 4.8 percent.

Table 8

SUMMARY OF ESTIMATED BUILDING-RELATED C&D DEBRIS GENERATION, 1996*
(Roadway, Bridge, and Land Clearing Debris not included)
(Thousand Tons)

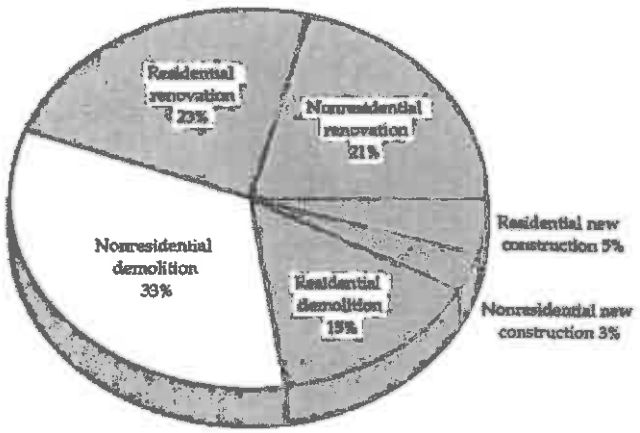
Source	Residential		Nonresidential		Totals	
	Thou tons	Percent	Thou tons	Percent	Thou tons	Percent
Construction	6,560	11	4,270	6	10,830	8
Renovation	31,900	55	28,000	36	59,900	44
Demolition	19,700	34	45,100	58	64,800	48
Totals	58,160	100	77,370	100	135,530	100
Percent	43		57		100	

* C&D debris managed on-site should, in theory, be deducted from generation. Quantities managed on-site are unknown.

Source: Franklin Associates

The estimate of 136 million tons per year is equal to 2.8 pounds per capita per day (pcd). This compares to 4.3 pcd of MSW generation. Note that the 2.8 pcd does not include C&D debris from roadway and bridge construction and demolition or from land clearing projects. These wastes are discussed briefly in the following section.

Figure 3. Generation of construction and demolition debris from buildings



CONSTRUCTION AND DEMOLITION DEBRIS GENERATION FROM ROAD, BRIDGE, AND OTHER NON-BUILDING ACTIVITIES

In this initial characterization study, we developed a methodology to estimate C&D debris generation from building construction, demolition, and renovation. However, because point source data were not available, we did not estimate the generation of site clearance materials, excavated materials, and roadwork materials. These are waste streams that will require further investigation in future editions of EPA's C&D work. These other wastes are typically managed by many of the same processors and landfills that manage building-related wastes.

We have made attempts, however, to provide certain cameo examples of locally generated data on most of these other generating sectors within the context of this report. Most communities and states that report C&D debris include the total C&D debris stream, which of course varies according to applicable regulations and definitions.

In 1995, a report was completed for Anne Arundel County, Maryland (part of the Metro Washington, DC area) that attempted to quantify total C&D debris generated and/or disposed in that County (GBB 1995). The report concluded that 138,000 tons per year of in-County generated C&D waste was being disposed at area C&D landfills (called "rubblefills" in the State of Maryland), while 435,000 tons per year of C&D debris materials were processed/recycled. This latter figure was reported to be about 12 percent wood waste and 88 percent concrete, asphalt, brick, block and porcelain waste generated in the County. This particular report is significant in the sense that it represents an example of total C&D generation in a large developing community.

STATE CONSTRUCTION AND DEMOLITION DEBRIS GENERATION RATES

We identified six states that have C&D debris generation records available. They are California, Florida, Massachusetts, Oregon (Portland metropolitan area), South Carolina, and Vermont. Generation of C&D debris from these states ranged from 1.43 pcd in South Carolina to 3.41 pcd for Massachusetts.

All of these states except Massachusetts report rates lower than 2.8 pcd, which is our estimate for building-related debris alone. The state data may include road debris as well. There are several reasons some of the states' estimates may be low. The six states' data reflect reports from facilities receiving C&D debris. Some of the many locations typically accepting C&D debris—ranging from established landfills to processors to sites with temporary permits (or no permits)—may be missed when C&D debris quantities are reported. Also, C&D debris mixed with MSW may be missed. In some states, road debris (asphalt and concrete) is mostly reused or recycled; it either remains on site or is incorporated into other roads. Thus, very little road debris would be expected in the states' quantities.

It is important to note that the methodology used in this report includes all building-related C&D debris, whether managed in C&D or MSW landfills, processing centers, land clearing landfills, or unpermitted landfills. It also includes on-site managed waste, if any, e.g., concrete or asphalt that is used as fill material, since no method was determined for making a correction. An important feature of the methodology used for residential demolition debris estimation, i.e., changes in housing inventory, is that residential buildings destroyed by natural disasters are included in this estimate.

We contacted two of the states by phone to discuss their C&D debris generation estimates. Florida reported a generation rate in 1995 of 2.01 pounds per capita per day. This rate was determined from reports to the state by each of the counties. The waste reported consists primarily of building waste, and is thought by the official contacted to be under-reported by many of the counties (Moreau 1997).

South Carolina has a reported generation rate of 1.43 pcd. The person contacted thinks that number is also grossly under-reported (Pitt 1997). C&D debris landfills for utilities and manufacturing and short term landfills are not required to report their quantities in South Carolina, and are not monitored by the State.

COMPOSITION OF CONSTRUCTION AND DEMOLITION DEBRIS

Six sets of C&D sorting data that provide some empirical measurements of the composition of C&D debris were identified. Each of the sampling studies was conducted with the specific goal of developing composition data for C&D debris. Probably the most rigorous assessments have been conducted at residential construction sites. These waste assessment projects are:

1. The National Association of Homebuilders (NAHB) Research Center conducted waste assessments at four residential construction sites: Largo, Maryland; Anne Arundel County, Maryland; Portland, Oregon; and Grand Rapids, Michigan. The Research Center also conducted a waste assessment at a four-unit multi-family demolition (or deconstruction) site (NAHB 1997b).

2. The Metropolitan Service District in Portland, Oregon (METRO) conducted a series of sampling projects at a number of residential and nonresidential construction, demolition, and renovation sites in Oregon.

3. Cunningham Environmental Consulting and the Cascadia Consulting Group sampled loads of C&D debris at disposal sites and transfer stations. Loads of residential and commercial construction, demolition, and remodeling debris from the Seattle area were selected (Cunningham 1996). Detailed sorting of these loads was done.

4. Gershman, Brickner & Bratton, Inc. (GBB) conducted a C&D sorting study for the Town of Babylon, New York that was funded by the New York State Energy Research and Development Authority (NYSERDA). The three-week study included C&D samples from waste loads from all or parts of 16 residential and nonresidential construction, demolition, and renovation projects (Brickner 1993). A total of 161.5 tons were sorted.

5. GBB, in association with the Metro Waste Authority, also sampled C&D debris from residential and commercial construction, demolition, and remodeling projects in Des Moines, Iowa for a one-week period (Brickner 1995).

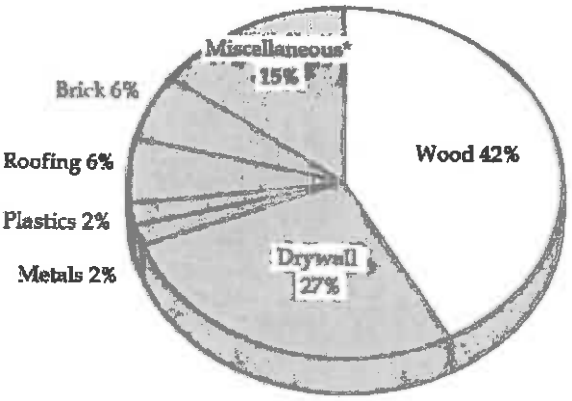
6. R.W. Rhine, Inc. of Tacoma, Washington, a demolition contractor, provided waste assessment data from the demolition of 19 nonresidential (industrial/commercial) buildings in the greater Northwest area.

In addition to the analyses listed above, the University of Florida is conducting waste audits at Florida residential construction sites. Data from these studies are expected to be available soon.

The detailed composition data from the sampling studies are shown in Tables A-11 through A-18 in Appendix A of this report. A review of these tables demonstrates that the composition of C&D debris is highly variable, as may be expected because of the many different types of buildings and construction practices in existence. The data collections were done under many different conditions and levels of detail. Therefore, we made no attempt to average all the compositions. Although different, there are some observations that can be made.

The first two (Tables A-11 and A-12) and sixth (Table A-16) sets of data characterize waste at the source, i.e., at specific construction or demolition sites. The other three data sets (Cunningham in the Seattle area and GBB in Babylon, New York and Des Moines, Iowa) characterize debris as disposed at the landfills. The sectors (or sources) for each load of C&D debris that was sorted are identified, but the specific phase of construction or demolition is not identified.

Figure 4. Sample composition of residential new construction debris (Average of assessments in four locations)



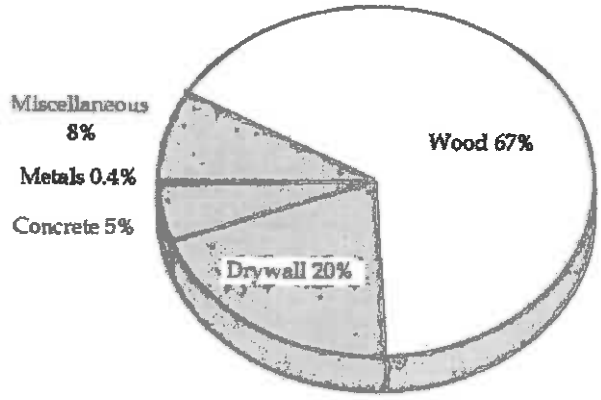
Source: NAHB Research Center * Refuse, dirt, sweepings, and aggregat

NAHB and Metro examined both composition and quantity per square foot of floor space for single-family housing. Both of these groups developed data from well-defined construction projects, i.e., the materials consist of trim scraps from beginning to end of the residential construction process, without serious contamination from other sources. Figures 4 and 5 show these data in percent by weight. Figure 4 shows the average composition for four single-family houses, two in the East, one in the Midwest, and one in the Northwest. Wood is the largest component, followed by drywall.

Figure 5 shows the composition from three new residential construction sites in the Portland, Oregon area. The percentage of wood in the Northwest samples is considerably higher, as may be expected, because a large fraction of homes in the Northwest have wood roofs. Residential construction debris in the Southwest and southern United States is expected to contain a lower percentage of wood than in the East and Midwest, and more brick and cinder blocks. As waste assessment data become available in other regions of the country, it will be possible to develop an overall composition for residential construction debris and to relate composition to total generation, i.e., estimate total C&D debris generation by material type.

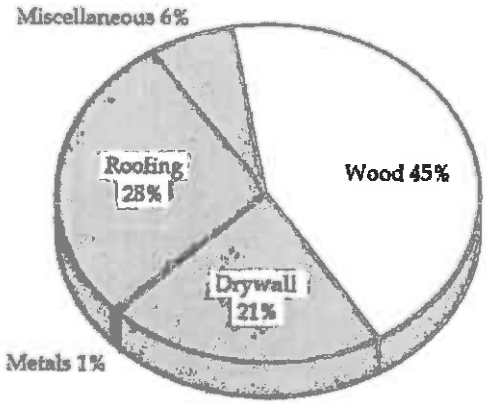
Figure 6 shows the composition of residential renovation debris in the Northwest. This stream is similar to the construction debris stream, but with an obvious difference, an increase in the amount of roofing materials. Only trim pieces of roofing are included in new construction debris.

Figure 5. Sample composition of residential new construction debris (Average of three sites, Portland, Oregon)



Source: METRO Portland, Oregon

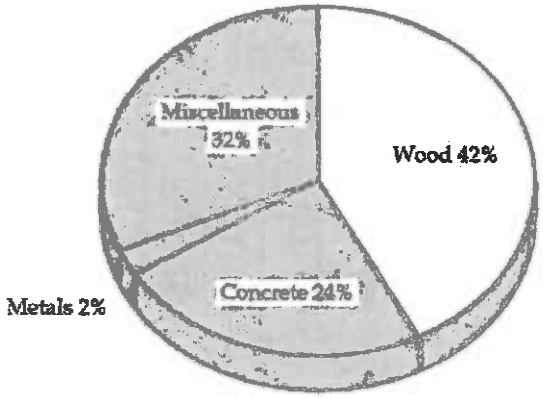
Figure 6. Sample composition of residential renovation debris (Average of two sites, Portland, Oregon)



Source: METRO Portland, Oregon

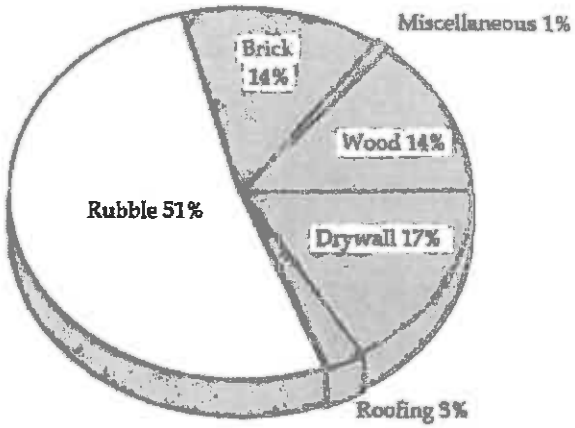
Concrete is missing from the renovation stream of Figure 6. Obviously these two projects did not include projects like driveway replacement. This demonstrates that many samples are required before we can report an overall composition that represents the U.S. average with confidence.

Figure 7. Sample composition of residential demolition debris (Average of three sites, Portland, Oregon)



Source: METRO Portland, Oregon.

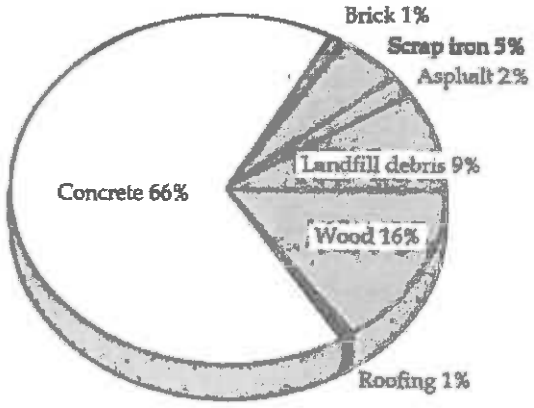
Figure 8. Sample composition of multi-family demolition debri



Source: NAHB Research Center, Inc.

Figure 7 displays the composition of residential demolition debris. Concrete is an obvious component of this stream, as it is in Figure 8, which shows the composition of a 2,000 square foot two story four-plex that was disassembled by NAHB in a demonstration project for the USEPA.

Figure 9. Sample composition of demolition debris (19 nonresidential projects in the Pacific Northwest)



Source: R.W. Rhine, Inc., Tacoma, WA

Figure 9 shows the average composition of 19 nonresidential buildings that were demolished in the Northwest area. These were large industrial/ commercial type buildings that ranged in weight from 891 tons to 37,500 tons. While this figure represents the average composition, the percentage of wood ranged from 0.03 percent to 88 percent in the 19 buildings. This demonstrates the huge variability of building types.

Some general observations can be made from these figures. Residential construction and renovation projects tend to yield significant quantities of wood and drywall, whereas demolition sites are heavily weighted toward concrete and rubble. The debris from 19 nonresidential demolition projects of Figure 9 averaged 66 percent concrete.

Chapter 3

MANAGEMENT OF CONSTRUCTION AND DEMOLITION DEBRIS IN THE UNITED STATES

INTRODUCTION

Construction and demolition (C&D) debris is managed in a variety of ways, ranging from reuse to recycling to disposal in landfills or combustion facilities. The most common management method is landfilling, including specially permitted C&D landfills and municipal solid waste (MSW) landfills, as well as unpermitted inert debris sites.

In most states there is no formal reporting mechanism that documents C&D debris disposal, recovery, or recycling activities. The information collected by many state agencies is largely anecdotal. In addition, information from private companies is generally considered to be proprietary and not available for public dissemination.

LANDFILLING

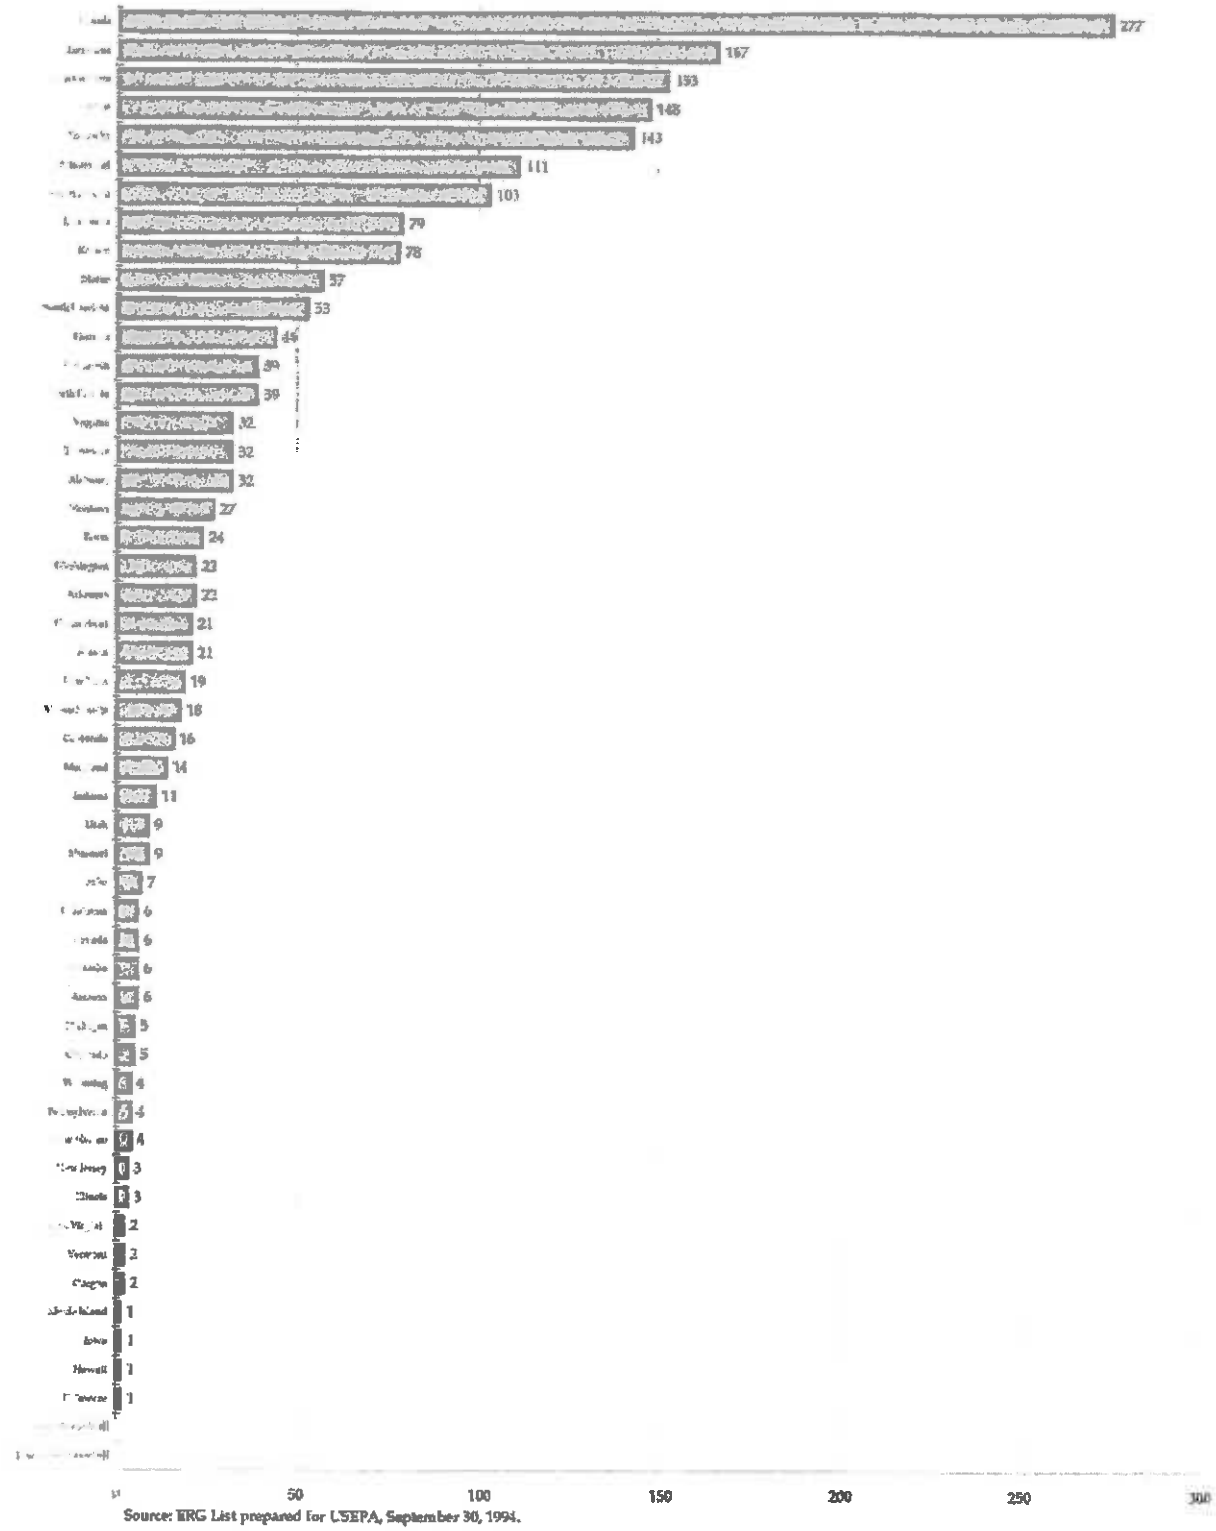
A large fraction of C&D debris generated in the United States ends up in C&D landfills. Since much of this waste stream is inert, solid waste rules in most states do not require the landfills to provide the same level of environmental protection (liners, leachate collection, etc.) as landfills licensed to receive MSW. Therefore, C&D landfills generally have lower tipping fees, and handle a large fraction of the C&D debris.

A 1994 survey done for the EPA identified about 1,900 active C&D landfills in the United States (ERG 1994). Florida had the largest number (280), followed by six other states (Louisiana, North Carolina, Ohio, Kentucky, Mississippi, and South Dakota) with over 100 C&D landfills apiece. (See Appendix A, Table A-19 and Figure 10.)

A recent survey of 850 randomly selected C&D landfills in the United States (40 percent response rate) found that on average, C&D landfills received 29,300 tons of material in 1995 (Bush 1997). Assuming that average holds true for the 1,900 active landfills, 55.6 million tons per year are disposed of in permitted C&D landfills. This amount is equal to about 41 percent of the estimated 136 million tons of building related C&D debris, as estimated in the previous chapter. However, this 55.6 million tons is likely to contain significant amounts of non-building C&D debris.

The amount of C&D debris disposed of in MSW landfills is not known. It is significant, however, because in many areas, particularly where landfill tipping fees are low, disposal in MSW landfills is the most common management method for C&D debris.

Figure 10. Number of C&D debris landfills in the United States



Source: ERG List prepared for USEPA, September 30, 1994.

A significant fraction of residential renovation debris is discarded by homeowners into the household trash and disposed of in MSW landfills. Discarded items include replacement plumbing and electrical fixtures, lumber, and other building materials used in home repair or improvement projects.

Unpermitted landfills for C&D debris are also very common in many states. These are fill areas for inert materials, with little or no control or record keeping by the state or local governments. Some of these are on-site facilities that are used only for the disposal of C&D debris generated at a specific site and may be closed following completion of the activity. Little data exists on the number of unpermitted C&D landfills nationwide. Georgia, the only state known to count them, has about 900 such sites (ICF 1995).

Open burning of C&D debris at construction sites is practiced in many rural areas as well as in many small to medium size cities. The amount of material burned is unknown.

Regulatory schemes used by states for C&D landfills have been divided into four categories as summarized in Table 9. Eleven states require C&D landfills to meet state MSW landfill requirements or requirements similar to these. Twenty-four states regulate C&D landfills separately from MSW landfills. In addition to the 24 states that regulate all C&D landfills as a landfill unit separate from sanitary landfills, eight states have defined further separate requirements for on-site and off-site C&D landfills. Of those eight states, Maine requires both off-site and on-site landfills to meet MSW landfill rules if they are greater than six acres. Seven states exempt all on-site landfills from regulatory requirements. Of these seven, sanitary landfill regulations apply to all off-site landfills in Colorado and New Mexico.

In summary, disposal in landfills is the major waste management option for C&D debris from buildings. We estimate that C&D, MSW, and other landfills account for roughly 65 to 85 percent of that waste stream.

RECOVERY OF C&D DEBRIS FOR RECYCLING

The six major constituents of C&D debris, if not too severely contaminated, have all been recovered and processed into recycled-content products that have been marketed somewhere in the United States. The materials most frequently recovered and recycled are concrete, asphalt, metals, and wood. To a much lesser degree, gypsum wallboard and asphalt shingles have been processed and recycled. The technologies to recover and process these materials for reuse are available. The major barriers to increased recovery rates at this time are:

Table 9

- the cost of collecting, sorting, and processing;
- the low value of the recycled-content material in relation to the cost of virgin-based materials, and
- the low cost of C&D debris landfill disposal.

Responses to a survey of North American aggregate producers indicated that plant permitting issues, as well as product specifications that favor the use of virgin materials, were also problems facing recyclers (Deal 1997).

The number of recycling facilities for C&D debris has been growing rapidly in the last few years. In 1996, it was estimated there were at least 1,800 operating C&D recycling facilities (Brickner 1997). That number includes more than 1,000 asphalt and concrete crushing facilities, 500 wood waste processing plants, and 300 mixed-waste C&D facilities. No information is available on the average throughput of these facilities.

The estimate of 1,800 C&D facilities does not include quarry rock crushing plants, brush/tree tub grinding plants, or pallet grinding operations. The asphalt and concrete crushing plants handle large quantities of road debris, but also concrete recovered from building construction, renovation, and demolition.

The largest number of C&D recycling facilities were reported to be in the Western States (28 percent) and the Mid-Atlantic states (27 percent). The Southwestern and Rocky Mountain States each have only three percent of the total, and the Southeastern, Upper Midwestern, and New England states have 12, 13, and 14 percent of the facilities, respectively.

Because of the effort being exerted to develop markets for recovered materials, the number of C&D recycling facilities is continuing to grow. A July 1997 status update lists 37 new recycling plants or equipment additions in the United States, including planned projects for the rest of 1997 (Leiter 1997). The editor of **C&D Debris Recycling** estimates there are now more than 3,500 C&D debris recycling facilities in operation (Turley 1998).

Deconstruction

Deconstruction is a new expression to describing the process of selective dismantling or removal of materials from buildings before or instead of demolition (NAHB 1996a). A common practice in the United States is to remove materials of value from buildings prior to and during demolition for recycling or reuse. Reuse and recycling examples include electrical and plumbing fixtures that are reused, steel, copper, and lumber that are reused or recycled, wood flooring that is remilled, and doors and windows that are refinished for use in new construction.

Demolition contractors have been practicing deconstruction in varying degrees for a number of years to remove some of the more valuable materials prior to demolition by conventional methods. This activity, along with recovery of demolition materials after the building has been knocked down, has increased significantly since the 1970s and 1980 (Taylor 1997). Deconstruction minimizes contamination of demolition debris, thus increasing the potential for marketing the recovered materials. It is, however, labor intensive, and may require more time than traditional demolition.

Several deconstruction demonstration projects have been completed recently, showing that high diversion rates may be achieved. The NAHB Research Center completed the deconstruction of a two-story, four-unit apartment building in Maryland (NAHB 1997). The Research Center measured the volume and the weight of all materials on site, whether salvaged, recycled, or landfilled. The diversion rate was 76 percent by weight and 70 percent by volume.

In another recent demonstration project, three buildings were deconstructed at the recently closed Fort Ord Army Base, located in Monterey County, California (Schneider 1997). The buildings included a one-story clinic, a single-story administration building, and a two-story barracks. Goals of this project include the evaluation of costs and potential recovery.

Asphalt and Concrete Recycling

Concrete is made up of cement, water, and aggregate, such as crushed stone, sand, or grit. Concrete can be recycled by first crushing it to remove any metals. The primary use of crushed concrete is as a replacement for road-base gravel. Other applications include use as an aggregate in asphalt or concrete. Concrete recycling is practiced in most areas of the country. The practice is most prevalent in areas where landfill tipping fees are high or aggregate is in short supply.

Asphalt pavements are made of asphalt concrete (AC), which consists of asphalt (the bituminous binder) and aggregate. The aggregate makes up the bulk of the asphalt concrete, while the asphalt binder comprises about 5 to 7 percent CIWMB 1997).

While no reports have been identified showing the amount of asphalt and concrete recycled, some datapoints that provide indications of the amounts recycled are discussed below (Brickner 1997).

As stated above, it is estimated there are more than 1,000 asphalt and concrete crushing facilities in the United States. GBB estimates that potentially 50 million tons per year of milled pavement in the United States is reused. Twenty to 50 percent goes back into pavement as Reclaimed Asphalt Pavement (RAP), with the remainder finding its way into aggregate base or subbase. GBB research in the Pacific Northwest, for example, has estimated that for the State of Washington alone, the use of RAP is between 650,000 and 1,000,000 tons per year.

Based on data collected for the State of Washington from waste concrete processors/recyclers, GBB has estimated that 1.4 to 1.5 million tons of waste concrete in that state are recovered, crushed, and recycled on an annual basis.

In Anne Arundel County, Maryland, an area between Washington, DC and Baltimore, Maryland, GBB field work in 1995 indicated that the concrete and asphalt processors in that County alone were receiving, crushing and recycling over 850,000 tons per year of these two types of materials (includes out-of-county generation).

In California, asphalt pavement and concrete are not reported separately. The state estimated generation of "inert solid waste," which consists of concrete, asphalt, dirt, brick and other rubble, at 8.2 million tons per year. The estimated recycling rate for inert solid wastes is 57 percent; the remainder is disposed of (CIWMB 1997).

Waste Wood Recycling

Wood waste produced at construction sites generally has a better potential for reuse than wood from demolition sites due to the ease of separating the materials. Demolition wood is often less desirable because of contamination and because of the difficulty in separating the wood from other building materials.

Wood processing facilities have sprung up in many areas of the United States in recent years, particularly in areas with high landfill costs. Many of these facilities accept wood from C&D debris as well as other wood. Processed (chipped) wood is used as mulch, composting bulking agent, animal bedding, and fuel. Wood waste from construction or demolition is attractive as a fuel because of its low moisture content. Depending on the wood waste boiler system design and the state/regional air pollution permit requirements for the facility, a level of quality control may be necessary at the wood processing plant to reduce and/or avoid the processing of treated and/or painted wood if used as a fuel source in a combustion process.

The American Forest & Paper Association (AF&PA) has located 315 wood processing facilities in the United States that process C&D debris, as shown in Table A-20 of the Appendix. These facilities were included in the estimate of 500 wood processing plants as discussed above. The leading states for these wood processing plants are North Carolina (44), Oregon (35), and California (34). Quantities of wood processed are not given in the AF&PA report.

Metals Recycling

Metals have the highest recycling rates among the materials recovered from C&D sites. Good markets for ferrous metals, as well as copper and brass, have existed for many years. The Steel Recycling Institute estimates the recycling rate for C&D steel is about 85 percent (18.2 million tons out of 21.4 million tons generated). These numbers include not only scrap steel from buildings but also from streets, bridges, and highways (Heenan 1996). The percentage of metals coming from roads and bridges is unknown.

A 1997 survey of North American aggregate producers by Vanderbilt University and C&D Recycling Magazine found that the markets for waste rebar removed from the concrete rubble appear to have increased from 1994 to 1997 (Deal 1997). Twenty-one percent of the 1994 recyclers depended on disposal for their rebar compared to 4 percent in 1997.

Asphalt Shingles

Asphalt shingles are most commonly used on slanted residential roofs. Built-up roofing, which consists of roofing felt between layers of tar and gravel, is traditionally used on flat commercial roofs. These two materials represent the majority of the waste coming from roof replacement or repair. About two-thirds of the residential roofing market is made up of asphalt shingles (NAHB 1996b). Other roofing materials include wood, tile, and concrete.

The common uses for recycled roofing asphalt include hot mix asphalt for paving, cold mix asphalt paving product, and new roofing materials. Meeting the specifications for paving and roofing materials is still limiting the growth of these applications. Preconsumer manufacturing scrap (approximately one million tons per year) is currently being used in hot mix asphalt; however, postconsumer scrap (estimated at 8 to 10 million tons per year), which is less uniform in composition, is not nearly as widely used or recommended for use in hot mix asphalt (Button 1997).

Drywall (Sheetrock, Gypsum)

Drywall is being recycled in several locations by first separating the paper backing, which is recycled into new paper backing, and then remixing the gypsum and using it in the manufacture of new drywall. Recovered drywall has also been used as animal bedding, cat litter, and as a soil amendment.

Estimated Recovery Rate

Because of the relatively benign nature of C&D debris (i.e., much of it is inert), there has been no concerted effort in the past to track and quantify the generation or recovery rate from a national perspective. Therefore, only general estimates can be made based on data from those local communities and states that monitor the waste stream.

A total survey of states was not feasible for this project, but several states were contacted in an attempt to estimate of the national recovery rate for C&D debris. States representing more than 50 percent of the U.S. population were contacted. Most states contacted have no statewide records available on the quantity of C&D debris generated or recovered for recycling. We identified five states that report recycling rate data for C&D debris. The recovery rates in the five states range from 37 percent to 77 percent. The five states and their reported recovery rates are:

Massachusetts	77 percent
Florida	46 percent
Vermont	37 percent
Oregon (Metro)	42 percent
South Carolina	40 percent
Average	48 percent

These data confirm that there is significant recovery of C&D debris for recycling in these locations. However, it is not likely that these five states are representative of the United States as a whole. We expect that the states that keep records have higher recovery rates than the national average.

The definitions of what constitutes C&D debris and what constitutes recycling among the states are not standardized, as was discussed earlier, although most C&D debris definitions include both building-related wastes and as road and bridge debris. Massachusetts includes asphalt and concrete from roads in both the numerator and denominator of the recovery rate calculation, but does not include land clearing debris, (i.e., stumps, soil, rock, etc.). Florida's recovery numbers include primarily building debris and land clearing debris. Road debris is generally not counted (Moreau 1997).

Several methods were explored for estimating a national recovery rate for C&D debris. The first is to look at the relationship of recovery rate and landfill tipping fees. It might be expected that states with low C&D landfill tipping fees have lower recovery rates.

Lowest C&D landfill tipping fees are generally in the lower population density states, such as the Midwest, where the average has been reported at $19.70 per ton, compared to $46 and $42.60 per ton in the Northeast and West, respectively (Bush 1997). A large number of states in the Midwest do not have recovery rate records. In the South, the average is $27.10 per ton. Using tipping fees as a guide, a conservative estimate would be that the average recovery rate might be about half of the average of the five states reporting recovery rates, or 20 to 30 percent of generation.

To test how reasonable the 20 to 30 percent estimate is, consider the 1,800 C&D debris recovery facilities referred to above. Assuming the 1,000 concrete and asphalt plants handle primarily road debris, there are 800 or more wood and mixed waste processors that are thought to handle primarily building debris. Recycling rates of 20 to 30 percent (27 to 41 million tons per year) would result in an average throughput of 90 to 140 tons per day, which appears to be a reasonable average size.

SUMMARY OF C&D DEBRIS MANAGEMENT PRACTICES

Over the past 10 years a significant amount of data has been collected on the amount of C&D debris disposed of at C&D and MSW landfills and the amount processed at recycling facilities. The studies were conducted at the municipal, county, or state levels. Research has also been conducted on the number of C&D landfills and processing facilities in operation on the national level. This foundation of new research was used to estimate how C&D debris is managed on a national level.

Table 10 summarizes our estimated C&D debris management practices in the United States in 1996. These quantity estimates apply to building-related wastes, as estimated in Chapter 2. An estimated 35 to 45 percent of the waste generated is managed in C&D landfills, 20 to 30 percent is recovered for recycling, and 30 to 40 percent is disposed of in MSW landfills and other disposal sites, such as unpermitted landfills or combustion facilities.

Table 10
ESTIMATED MANAGEMENT OF BUILDING-RELATED C&D DEBRIS IN THE UNITED STATES, 1996

Management Option	Million tons/year	Percent of Total
Recovered for recycling	25-40	20-30
C&D landfills	45-60	35-45
MSW landfills and other*	40-55	30-40
Totals	136	100

* Includes combustion and disposal in unpermitted sites.

Chapter 4

ADDITIONAL PERSPECTIVES ON CONSTRUCTION AND DEMOLITION DEBRIS

INTRODUCTION

The solid waste industry usually identifies wastes according to the source and predominant method of solid waste management. Waste materials defined as municipal solid waste (MSW) are normally discarded from residences or commercial establishments and managed in municipally controlled landfills or processing facilities. Construction and demolition (C&D) debris is generated at construction and demolition sites, and managed in C&D landfills or processing facilities.

However, the lines separating the various sectors of solid waste are sometimes blurred. Data sources for the production of some components of MSW (e.g., paper products) are developed from trade association data. These sources tabulate the entire production, without regard to the final discard point; i.e., some paper products are not discarded from residences or commercial establishments, but are collected from construction sites. Conversely, some wastes that are classified as C&D debris by the methods developed in this report, because they are building materials, are placed into the household trash and end up in MSW landfills.

While this blurring of lines may not be an issue of great importance because of the relatively small amounts of crossover, it could potentially result in double counting of some fractions when estimating the national generation.

MSW COLLECTED WITH C&D DEBRIS

Definitions for some components that make up MSW are affected by the data that are available. For example, postconsumer old corrugated containers (OCC) are included in EPA's MSW characterization, even though some of them are discarded from construction sites. Light fixtures, major appliances, vinyl siding, and other items are often delivered to construction sites in corrugated boxes. As a result, nearly all construction site waste assessments include OCC as a waste category. On a volume basis, up to 20 percent of wastes collected at residential construction sites may be OCC. By weight, OCC ranged from 2 percent to 10 percent in the waste audits performed by NAHB.

An extensive year-long demonstration project conducted by CornerStone of Wisconsin, Inc. was monitored on a quarterly basis by GBB (Brickner 1997). GBB reported that through the use of specialized collection vehicles serving new residential construction in Southeast Wisconsin, the amount of collected and marketed OCC averaged about 25 percent of the total collected volume of material. Since the loose corrugated containers were estimated to occupy about 30 cubic yards per ton, the actual weight recovered was estimated to be 7 percent of the total average weight of material generated from each of the residential units serviced by the unique CornerStone system.

Additional data on several other C&D debris sorts that also quantified OCC are presented in Appendix A of this report.

Although the amount of OCC collected at C&D sites can be a significant fraction of residential construction wastes, it is a small fraction of the total OCC discarded, and on a weight basis it represents a very small fraction of the total C&D debris stream.

Other common MSW items typically collected at C&D sites include food and beverage containers, appliances, and carpeting. Containers discarded by workers at construction and demolition sites typically show up in C&D debris. Major appliances and carpeting also frequently remain in houses that are demolished, and are included with mixed C&D debris.

C&D DEBRIS COLLECTED WITH MSW

Significant quantities of building materials, particularly renovation scraps, are also discarded in the municipal waste stream. Examples include pipes, plumbing fixtures, and building materials that are replaced by the residents and discarded with their household trash. The amount of these types of wastes in MSW is not known. However, this "overlap" of MSW and C&D may account for some of the discrepancies that have been experienced between expected MSW quantities and actual weights.

At the current level of refinement of C&D generation and recovery data, the overlap of MSW and C&D debris is not expected to be a cause for concern at the national level in the near future.

CALCULATIONS

Table A-1
Residential Construction Debris Worksheet

Method to Use

(1) Start with total dollars of new construction, from Census Bureau. Current Constr Reports, C-30.
(2) Calculate sq ft of new construction from total dollars and $/sq ft construction cost.
(3) From empirical waste assessment, estimate lb/sq ft of new construction.
(4) Calculate total generation.

Calculation

(1) C-30, Residential Construction (1996) = $181,795,000,000
(Includes private new housing units and public housing & redevelopment)

(2) 1995 Census data, Table 1175 of 1996 Stat Abs. (Note: whole industry not included)

Residential Construction	$127,900,000,000	
Residential sq ft of new constr	2,172,000,000	sq ft
Cost of new construction	$58.89	per sq ft

Total sq ft of new constr = 181,795,000,000/58.89/1.03 2,997,326,036 sq ft
(Includes 3 percent inflation factor)

(3) See sampling waste assessment results:

Average Generation = 4.38 lb/sq ft

(4) Total new residential construction debris = 6,564,000 tons/year

Table A-2
Nonresidential Construction Debris Worksheet

Method to Use

(1) Start with total dollars of new construction, from Census Bureau. Current Constr Reports, C-30.
(2) Calculate sq ft of new construction from total dollars and $/sq ft construction cost.
(3) From empirical waste assessment, estimate lb/sq ft of new construction.
(4) Calculate total generation.

Calculation

(1) C-30, Nonresidential Construction (1996) $198,694,000,000
(Includes all private nonres and public industrial, educ, hosp & other)

(2) 1995 Census data, Table 1175 of 1996 Stat Abs. (Note: whole industry not included)

Nonresidential Construction	$112,000,000,000	
Nonresidential sq ft of new construction	1,276,000,000	Sq ft
Cost of new construction	$87.77	per sq ft

Total sq ft of new construction = 198,694,000,000/87.77/1.03
(Includes 3 percent inflation factor) 2,197,759,570 sq ft

(3) See sampling waste assessment results:

Generation = 4.02 lb/sq ft

(4) Total new residential construction debris = 4,417,000 tons/year

Table A-3
Residential Demolition Worksheet

Method to Use

(1) Start with the number of residences demolished per year.
(2) Estimate the average size of residences that are demolished (single-family (SF) and multi-family (MF)).
(3) Estimate pounds of waste generated per sq ft, from sampling studies.
(4) Calculate total generation.

Calculation

(1) Estimate: 245,000 residential demolitions per year, per NAHB Economics Dept.

(2) Smaller than the average size of new residences, because it is older.
See graph of sizes of houses built, in Figure 2:
New houses built in 1995 are 2,100 sq ft (SF), and 1,050 sq ft (MF)
New MF house sizes are unchanged since 1975, while new SF houses grew from 1,600 sq ft to 2,100 sq ft
Ave size is 1,396 sq ft from 1975 to 1986, then climbs to 1,900 sq ft/house
Demolitions: use 1600 sq ft for SF houses and 1000 sq feet for MF houses

(3) METRO sampling of three SF houses = 49.5 lb/sq ft without concrete	39.6	tons	31%
Estimated wt of foundation, 30' X 30' house w/8" thick basement walls			
30'X8'X0.67'X4X150 lb/cu ft/2000 = est. tons of foundation	48.2	tons	38%
(assumes 8 in. wall thickness and concrete density of 150 lb/cu ft)			
Basement floor			
30'X30'/3X150 lb/cu ft/2000 = tons of floor	22.5	tons	18%
Garage floor & driveway 10X(20+45)/3X150/2000	16.3	tons	13%
Total for 1600 sq ft single family with full basement & garage	126.6	tons	100%
Total in lb/sq ft	158.2	lb/sq ft	
Concrete only	108.7	lb/sq ft	
For house on slab (basic house)	39.6	tons	51%
Concrete slab (same as basement floor)	22.5		29%
Garage floor & driveway (same as above)	16.3		21%
Total for SF on slab	78.35	tons	100%
Total in lb/sq ft	97.9	lb/sq ft	
Concrete only	48.4	lb/sq ft	
For house with crawl space (no bsmt, garage, or driveway)	39.6	tons	
Total for SF with crawl sp	49.5	lb/sq ft	
Concrete only	0.0	lb/sq ft	
For MF housing (per NAHB MF (Table 5))	127	lb/sq ft	

(4) Fraction of total units in U.S. from 1996 Statistical Abstract, Table 1194, Existing housing (1993)
Single family residences:

Foundation type	Fraction of total units	C&D debris (lb/sq ft)	Sq ft/unit	Est. units demol-ished	Total Sq ft	Generation (tons)	Percent of waste
Basement	0.30	158.2	1,600	72,426	115,882,000	9,200,000	47%
Concrete slab	0.17	97.9	1,600	42,406	67,850,000	3,300,000	17%
Crawl sp & other	0.19	49.5	1,600	46,865	74,983,000	1,900,000	10%
	0.66			161,697	258,715,000	14,400,000	73%
Weighted ave. SF residence		111.3	1,600				
Multi-family (>1)	0.34	127.0	1,000	83,303	83,303,000	5,300,000	27%
Totals	1.00			245,000	342,018,000		100%
Total residential demolition generation =						19,700,000	tons
Average pounds per sq ft of house demolished =						115	lb/sq ft
Average tons per dwelling unit demolished =						80.4	tons/unit

Source: Franklin Associates

Table A-4
Nonresidential Demolition Worksheet

Method to Use

(1) Start with the number of demolitions per year.
(2) Estimate the average size of nonresidential buildings demolished, assuming buildings demolished were built between 1920 and 1969.
(3) Estimate pounds of waste generated per sq ft, from sampling studies.
(4) Calculate total generation.

Calculation

(1) Use demolition permits data from the U.S. Bureau of the Census.
Note: Census permits data are discontinued as of 1995.

Census no. for 1994 = 45,061 buildings
Census no. for 1995 = 43,795 buildings

(2) Calculation of the average size of nonresidential buildings built between 1920 and 1969

Construction period		No. of yrs in period	Bldgs built in period (thou)	Million sq ft	Average bldg size Sq ft/bldg
1990	1992	3	128	2,502	19,547
1980	1989	10	884	14,287	16,162
1970	1979	10	982	14,014	14,271
1960	1969	10	783	12,612	16,107
1946	1959	14	880	10,421	11,842
1920	1945	26	724	8,712	12,033
1900	1919	20	255	3,608	14,149
Before	1989		169	1,721	10,183
1920	1969	50	2,387	31,745	13,299

The average size of buildings built between 1920 and 1969 = 13,299

Source: U.S. Energy Information Administration, "Commercial Buildings Characteristics,1992". From 1996 Statistical Abstract, Table 1206. (Excludes buildings 1,000 square feet or smaller).

(3) Average generation from sampling (Table 6) 173 lb/sq ft

(4) Total nonresidential generation 50,400,000 Tons

Source: Franklin Associates

Table A-5
Residential Renovation Worksheet

Method to Use

(1) Start with total dollars of improvements and repairs, from Census Bureau. Current Constr Reports, C-30.
(2) Estimate the number of replacements of roofs, driveways, HVAC, kitchens, etc. and the amount of waste materials generated from each.
(3) Calculate total generation.

Calculation

(1) 1996 Expenditures for improvements and repairs of residential properties — 114,300 million dollars
Census data, released 8/4/97

Improvements	68	percent	77,724
Repairs	32	percent	36,576
			114,300 million dollars

(2) Estimates for remodeling *	Million jobs	Tons/job	Tons
Kitchens (minor)	1.25	0.75	937,500
Kitchens (major)	1.25	4.5	5,625,000
Baths (minor)	1.8	0.25	450,000
Baths (major)	1.2	1.00	1,200,000
Additions	1.25	0.75	937,500

(3) Replacements (see FAL estimates, on following Tables A-7 through A-10)

Concrete from driveway replacements	13,000,000	tons/year
Asphalt roofs	6,800,000	
Wood roofs	1,400,000	
Heating & A/C replacements	1,574,000	
Kitchen remodeling	6,562,500	
Bathroom remodeling	1,650,000	
Additions	937,500	
Total residential renovation debris	31,924,000	tons/year

* NAHB Research Center

Source: Franklin Associates

Table A-6
Nonresidential Renovation Worksheet

Method to Use

(1) Start with total dollars of improvements and repairs, from U.S. Census.
(2) Calculate average $/sq ft of renovation from nonresidential renovation waste assessments.
(3) Generation (tons)=[Total Dollars / (Dollars/sq ft)] X (lb/sq ft) / (lb/ton).

Alternative method: Simply multiply quantity of residential renovation debris (Table A-5) by the ratio of dollars spent nonresidential to residential.

Calculation

(1) Total nonres improvements in 1996 * 100,400 million dollars
This compares to 1996 residential improvements of 114,300 million dollars
Total res + nonres 214,700 million dollars
*Assume same ratio of res/nonres as in 1992.
Bureau of the Census, Expenditures for Nonresidential Improvements and Repairs: 1992
From Table E: Comparison of Resid & Nonres Improvements & Repairs: 1992

	Tot. Dollars	Sq ft	$/sq ft		
(2) Renovation assessments	$8,578,000	72,000	$119	/sq ft	28.49 lb/sq ft
	$12,305,422	180,000	$68	/sq ft	6.85
	$2,100,000	24,000	$88		20.63
	$22,983,422	276,000	$83	/sq ft	17.67 lb/sq ft

(3) Total estimated square feet of renovation = 100,400 million / ($83/sq ft) 1,206 million sq ft

Estimated generation (method one) = 1,206 million X 17.67lb/sq ft/2,000 lb/ton = 10,652,000 tons/yr
Note: Total floorspace of nonresidential buildings in 1992 is 67.876 billion sq ft
Therefore 1,206 million represents 1.7 percent of total.
This seems to be unreasonably low. It implies an average of more than 50 years between renovations.
Therefore, use the alternative methodology.

Alternative methodology: Estimated generation = 31,924,000 / 114,300X100,400 = 28,042,000 tons/yr

Source: Franklin Associates

Appendix B

STATE DEFINITIONS FOR CONSTRUCTION AND DEMOLITION DEBRIS

Appendix B

STATE DEFINITIONS FOR CONSTRUCTION AND DEMOLITION DEBRIS

This appendix includes a representative sample of definitions of construction and demolition (C&D) debris used by states and other jurisdictions. The definitions are the most recent available from the states.

STATE OF CALIFORNIA

Construction and demolition (C&D) debris includes concrete, asphalt, wood, drywall, metals, and many miscellaneous and composite materials. C&D debris is generated by demolition and new construction of structures such as residential and commercial buildings and roadways.

STATE OF FLORIDA

"Construction and demolition debris" means discarded materials generally considered to be not water soluble and non-hazardous in nature, including but not limited to steel, glass, brick, concrete, asphalt material, pipe, gypsum wallboard, and lumber, from the construction or destruction of a structure as part of a construction or demolition project or from the renovation of a structure, including such debris from construction of structures at a site remote from the construction or demolition project site. The term includes rocks, soils, tree remains, trees, and other vegetative matter which normally results from land clearing or land development operations for a construction project; clean cardboard, paper, plastic, wood and metal scraps from a construction project; effective January 1, 1997, except as provided in Section 403.707(13(j), F.S., unpainted, non-treated wood scraps from facilities manufacturing materials used for construction of structures or their components and unpainted, non-treated wood pallets provided the wood scraps and pallets are separated from other solid waste; and the commingling of wood scraps or pallets with other solid waste; and *de minimis* amounts of other non-hazardous wastes that are generated at construction or demolition projects, provided such amounts are consistent with best management practices of the construction and demolition industries. Mixing of construction and demolition debris with other types of solid waste will cause it to be classified as other than construction and demolition debris.
(Florida Department of Environmental Protection, Bureau of Solid and Hazardous Waste, Division of Waste Management. Solid Waste Management in Florida. Classification of Landfills. Rule 62-701.200 (19). June 1997)

STATE OF HAWAII

"Construction and demolition waste" means solid waste, largely inert waste, resulting from the demolition or razing of buildings, of roads, or other structures, such as concrete, rock, brick, bituminous concrete, wood, and masonry, composition roofing and roofing paper, steel, plaster, and minor amounts of other metals, such as copper.

Construction and demolition waste does not include cleanup materials contaminated with hazardous substances, friable asbestos, waste paints, solvents, sealers, adhesives, or similar materials.
(Hawaii Department of Health. Hawaii Administrative Rules, Title 11, Chapter 58.1, Solid Waste Management Control)

STATE OF KANSAS

"Construction and demolition waste" means solid waste resulting from the construction, remodeling, repair and demolition of structures, roads, sidewalks and utilities; and solid waste consisting of vegetation from land clearing and grubbing, utility maintenance, and seasonal or storm-related cleanup. Such wastes include, but are not limited to, bricks, concrete and other masonry materials, roofing materials, soil, rock, wood, wood products, wall covering, plaster, drywall, plumbing fixtures, electrical wiring, electrical components containing no hazardous materials and non asbestos insulation. It shall not include asbestos waste, garbage, cardboard, furniture, appliances, electrical equipment containing hazardous materials, tires, drums and containers even though such wastes resulted from construction and demolition activities. Clean rubble that is mixed with other construction and demolition waste during demolition or transportation shall be considered to be construction and demolition waste.
(Kansas Department of Health and Environment. Kansas Statutes Annotated Chapter 65—Public Health, Article 34—Solid Waste and Administrative Regulations Article 29—Solid Waste Management, Part 1. Administrative Procedures; Part 2. Standards. May 1994)

STATE OF KENTUCKY

Construction/Demolition Debris Landfill - Construction/demolition debris landfill is the category of solid waste site or facility for the disposal of solid waste that results from the construction, remodeling, repair, and demolition of structures and roads and for the disposal of uncontaminated solid waste consisting of vegetation resulting from land clearing and grubbing, utility line maintenance, and seasonal and storm-related cleanup. Such waste includes, but is not limited to bricks, shredded or segmented tires, concrete and other masonry materials, soil, rock, wood, wall coverings, plaster, drywall, plumbing fixtures, tree stumps, limbs, saw dust, leaves, yard waste, paper, paper products, metals, furniture, insulation, roofing shingles, asphalt pavement, glass, plastics that are not sealed in a manner that conceals other wastes, electrical wiring and components containing no liquids or hazardous metals that are incidental to any of the above and other inert waste as approved by the division. Asbestos-containing materials may be accepted only if the permit application includes procedures approved by the division to handle these materials.
(Kentucky Natural Resources and Environmental Pollution Control, Division of Waste Management. Permits Issued by the Division of Waste Management, I. Solid Waste Landfill Permits (Construction and Operation), Landfill Classifications: Construction/Demolition Debris Landfill)

MARICOPA COUNTY, ARIZONA

Construction debris is a general term used to describe a large class of solid wastes usually generated as a byproduct of the construction, demolition, or maintenance of residences, commercial or industrial facilities and infrastructure. Construction debris includes such materials as: broken concrete, asphalt, steel, aluminum, glass, brick, tile, paper, plastics, wood products, sheet rock, street sweepings and canal dredgings.
(Maricopa County, Arizona. Construction Wastes: Classification)

THE COMMONWEALTH OF MASSACHUSETTS

C&D waste is comprised of debris generated from construction, renovation, repair, and demolition of roads, bridges, and buildings and includes wood, steel, concrete, masonry, plaster, metal, and asphalt, but not wood from land-clearing, i.e. stumps, logs, brush, and soil, nor rock from excavations.
(The Commonwealth of Massachusetts Department of Environmental Protection. 310 CMR 16.00, Site Assignment Regulations for Solid Waste Facilities. 16.02: Definitions; Also 1997 Master Plan Update Draft, Non Municipal Solid Waste)

STATE OF MINNESOTA

Construction Wastes

"Building materials, packaging, and rubble resulting from construction, remodeling, repair, and demolition of buildings and roads."

Demolition Debris

"Solid waste resulting from the demolition of buildings, roads, and other man-made structures, including concrete, brick, bituminous concrete, untreated wood, masonry, glass, trees, rock, and plastic building parts. Demolition debris does not include asbestos."
(Minnesota Office of Environmental Assessment. Metropolitan Solid Waste Planning Policy. Draft 11/25/96)

STATE OF NORTH CAROLINA

"Construction" or "demolition" when used in connection with "waste" or "debris" means solid waste resulting solely from construction, remodeling, repair, or demolition operations on pavement, buildings, or other structures, but does not include inert debris, land-clearing debris or yard debris.
(North Carolina Division of Waste Management. GS 130A-290. DEFINITIONS (1) (4))

STATE OF NEBRASKA

"Construction and demolition waste" shall mean waste which typically results from construction or demolition projects and includes all materials which are the by-products of construction work or which result from demolition of buildings and other structures, including, but not limited to brick, concrete rubble, masonry materials, paper,

gypsum board, wood, rubber and plastics. Construction and demolition waste does not include friable asbestos-containing materials, liquid waste, hazardous waste, putrescible waste or furnishings from demolished structures.
(Nebraska Department of Environmental Quality. Title 132 - Integrated Solid Waste Management Regulations, Chapter 1 011. Effective date: May 14, 1994)

STATE OF NEW YORK

Construction and demolition (C&D) debris means uncontaminated solid waste resulting from the construction, remodeling, repair and demolition of utilities, structures and roads; and uncontaminated solid waste resulting from land clearing. Such waste includes, but is not limited to bricks, concrete and other masonry materials, soil, rock, wood (including painted, treated and coated wood and wood products), land clearing debris, wall coverings, plaster, drywall, plumbing fixtures, non asbestos insulation, roofing shingles and other roof coverings, asphalt pavement, glass, plastics that are not sealed in a manner that conceals other wastes, empty buckets ten gallons or less in size and having no more than one inch of residue remaining on the bottom, electrical wiring and components containing no hazardous liquids, and pipe and metals that are incidental to any of the above. Solid waste that is not C&D debris (even if resulting from the construction, remodeling, repair and demolition of utilities, structures and roads and land clearing) includes, but is not limited to asbestos waste, garbage, corrugated container board, electrical fixtures containing hazardous liquids such as fluorescent light ballasts or transformers, fluorescent lights, carpeting, furniture, appliances, tires, drums, containers greater than ten gallons in size, any containers having more than one inch of residue remaining on the bottom and fuel tanks. Specifically excluded from the definition of construction and demolition debris is solid waste (including what otherwise would be construction and demolition debris) resulting from any processing technique, other than that employed at a department-approved C&D debris processing facility, that renders individual waste components unrecognizable, such as pulverizing or shredding. Also, waste contained in an illegal disposal site may be considered C&D debris if the department determines that such waste is similar in nature and content to C&D debris.
(New York State Department of Environmental Conservation, Division of Solid & Hazardous Materials. 6 NYCRR Park 360 Solid Waste Management Facilities. Title 6 of the Official Compilation of Codes, Rules and Regulations. 360-1.2(b)(38). Effective November 26, 1996. Reprinted January 1997)

STATE OF OREGON

"Construction and Demolition Waste" means solid waste resulting from the construction, repair or demolition of buildings, roads and other structures, and debris from the clearing of land, but does not include clean fill when separated from other construction and demolition wastes and used as fill materials or otherwise land disposed. Such waste typically consists of materials including concrete, bricks, bituminous concrete, asphalt paving, untreated or chemically treated wood, glass, masonry, roofing, siding, plaster; and

soils, rock, stumps, boulders, brush and other similar material. This term does not include industrial solid waste and municipal solid waste generated in residential or commercial activities associated with construction and demolition activities.
(Oregon Department of Environmental Quality. Disposal Site Definitions)

PORTLAND, OREGON METROPOLITAN SERVICE DISTRICT
Construction Waste - Waste materials resulting from the construction, remodeling and repair of buildings and other structures.
Demolition Waste - Solid waste, largely inert, resulting from the demolition or razing of buildings, roads, and other man-made structures. Demolition waste consists of, but is not limited to, concrete, brick, bituminous concrete, wood, masonry, composition, roofing and roofing paper, steel, and amounts of other metals like copper. Plaster (i.e., sheet rock or plasterboard), any other non-wood material that is likely to produce gases or leachate during the decomposition process, and asbestos wastes are not considered to be demolition wastes.
(Portland, Oregon Metropolitan Service District, Solid Waste Department. Investigation of Alternative Markets for Recycled Wood. Prepared by International Resources Unlimited, Inc.)

STATE OF RHODE ISLAND
"Construction and Demolition (C&D) Debris" shall mean non-hazardous solid waste resulting from the construction, remodeling, repair, and demolition of utilities and structures; and uncontaminated solid waste resulting from land clearing. Such waste includes, but is not limited to wood (including painted, treated and coated wood and wood products), land clearing debris, wall coverings, plaster, drywall, plumbing fixtures, non-asbestos insulation, roofing shingles and other roofing coverings, glass, plastics that are not sealed in a manner that conceals other wastes, empty buckets ten gallons or less in size and having no more than one inch of residue remaining on the bottom, electrical wiring and components containing no hazardous liquids, and pipe and metals that are incidental to any of the above. Solid waste that is not C&D debris (even if resulting from the construction, remodeling, repair, and demolition of utilities, structures, and roads and land clearing) includes, but is not limited to, asbestos waste, garbage, corrugated container board, electrical fixtures containing hazardous liquids such as fluorescent light ballasts or transformers, fluorescent lights, carpeting, furniture, appliances, tires, drums, containers greater than ten gallons in size, any containers having more than one inch of residue remaining on the bottom, and fuel tanks. Also excluded from the definition of C&D debris is solid waste resulting from any processing technique that renders individual waste components unrecognizable, such as pulverizing or shredding, at a facility that processes C&D debris.
(State of Rhode Island Department of Environmental Management, Office of Waste Management. Rules and Regulations for Composting Facilities and Solid Waste Management Facilities Rule 1.3.47)

STATE OF SOUTH CAROLINA

"Construction and demolition debris" means discarded solid wastes resulting from construction, remodeling, repair and demolition of structures, road building, and land-clearing. The wastes include, but are not limited to, bricks, concrete, and other masonry materials, soil, rock, lumber, road spoils, paving material, and tree and brush stumps, but does not include solid waste from agricultural or silvicultural operations.
(South Carolina Department of Health and Environmental Control. Chapter 61. R. 61-107.11 Solid Waste Management: Construction, Demolition and Land-Clearing Debris Landfills. B. Definitions)

WASHINGTON STATE DEPARTMENT OF ECOLOGY

"Demolition waste" means solid waste, largely inert waste, resulting from the demolition or razing of buildings, roads and other man-made structures. Demolition waste consists of, but is not limited to, concrete, brick, bituminous concrete, wood and masonry, composition roofing and roofing paper, steel, and minor amounts of other metals like copper. Plaster (i.e., sheet rock or plaster board) or any other material, other than wood, that is likely to produce gases or a leachate during the decomposition process and asbestos wastes are not considered to be demolition waste for the purposes of this regulation.
(Washington State Department of Ecology Solid Waste and Financial Assistance Program, Chapter 173-304 WAC, Minimum Functional Standards for Solid Waste Handling)

Appendix C

TYPICAL CONSTRUCTION AND DEMOLITION DEBRIS CONSTITUENTS

Table C-1

TYPICAL CONSTRUCTION AND DEMOLITION DEBRIS CONSTITUENTS

Primary Inert Fractions
Asphalt
Brick
Cinder block
Concrete with rebar/wire mesh
Concrete without steel reinforcing
Masonite/slate
Tile-ceramic
Glass
Dirt/earth
Plastic sheet film
Plastic pipe
Porcelain, including bathroom fixtures
Metal-ferrous
Metal-nonferrous
Electrical wiring
Insulation-fiberglass
Plastic buckets/containers

High Organic Based Fractions
Ceiling tiles
Corrugated shipping containers
Insulation-treated cellulose
Insulation-sheathing
Pallets/spools/reels
Pressboard/chipboard
Roofing materials (e.g., roofing felt, asphalt shingles)
Dimensional lumber & shapes (clean)
Plywood, particleboard, oriented strandboard, etc.

Range of Composite Materials (may require special handling)
Carpeting
Carpet padding
Gypsum wallboard (mainly gypsum with paper backing)
Electrical fixtures (metal, light tubes/bulbs, ballasts)
Electrical switches
Rubber hosing/conduits
Tires (some with wheels)
Painted wood
Pressure treated wood
Wood composites

Subject: Comment: Central Monofill Services Conditional Use Permit

The Alaska Department of Environmental Conservation (ADEC) Solid Waste Program has been asked to submit official comment on the Central Monofill Services (CMS) Matanuska Susitna Borough (MSB) Conditional Use Permit (CUP) Application.

On page 17of 38 of the CMS MSB CUP application it states:
Alaska Department of Environmental Conservation (ADEC) reviewed the CMS Monofill Permit application for this site and has approved the permit conditioned upon receipt of the MSB CUP.

This issue was addressed in the application by CMS in response letter to you , dated May 12, 2014.

The ADEC Solid Waste Program has reviewed the CMS Inert Waste Monofill Permit application submitted January 12, 2013, including additional information submitted January 23, 2013. ADEC Solid Waste determined that the application was complete, and posted a public notice in the Frontiersman on March 12 & 15, 2013. No comment was received on the public notice.

Due to an error in the original public notice, which excluded the permitting of an Asbestos waste cell at the monofill, ADEC will be publishing an additional 30-day public notice in the near future.

At this time, NO DECISION has been issued by ADEC on the CMS Inert Waste Monofill Permit application other than it is complete based on our January 2013 regulations.

Thank you,
Lori

Subject: Central Monofill Services Conditional Use Permit Application

Central Monofill Services has submitted a conditional use permit application under MSB 17.60 for the operation of a monofill for the disposal of inert material. The inert debris will primarily be non-hazardous shredded residual recyclable waste material from construction and demolition waste. The proposed site is located on MSB Tax Parcels 17N02E18C010 (2840 S. Glenn Highway) and 17N02E19B006 (2560 S. Glenn Highway); within Township 17 North, Range 2 East, Sections 18 and 19, Seward Meridian.

The Planning Commission will conduct a public hearing concerning this application on Monday, December 1, 2014 at 6:15 p.m. in the Borough Assembly Chambers, 350 E. Dahlia Avenue, Palmer, Alaska.

Application material may be viewed on-line at www.matsugov.us and clicking on "Public Notices'. Application material may also be reviewed in the Borough Permit Center.

If you have questions or would like to submit comments please contact Susan Lee, Planner II, at 861-7862 or mail to MSB Development Services Division, 350 E. Dahlia Avenue, Palmer, AK 99645; fax 861-7876 or e-mail: slee@matsugov.us.

Comments Due 5 p.m., October 31, 2014.

Subject: Central Monofill CUP

Susan,

Comments on Central Monofill Services CUP:

1) Water Quality
Soils in the area to be used are very porous, loose gravels and glacial loess, and therefore offer little or no filtering capacity for fluids being emitted or drained from the fill. Without any liners, even a 10 foot separation from the water table may not be sufficient to prevent leakage and potential contamination of the water resources in the area. Consistent monitoring of wells in the area prior to and during operations should be required to determine if any water contamination is occurring. CMS included a water quality monitoring plan in their previous application but did not include a plan in this application. This is a serious oversight.

A condition should be applied to this permit to submit a thorough water quality monitoring plan and conduct inspections according to an approved plan. Any problems with water quality found during the monitoring program should be reported immediately to ADEC and MSB as well as to neighboring households who rely on wells.

2) Air Quality
This location is one of the windiest sites in the region since it is at the confluence of the Matanuska and Knik River valleys. Loose debris and dust from the fill will scatter beyond the boundaries of the site if deposited on windy days and not covered up immediately. The applicant proposes the use of catch fences and compactors to reduce windborne debris. They state "when sustained wind conditions on site exceed 20 mph, waste will not be unloaded without secondary containment". Even with secondary containment, strong winds in this area will cause blowing debris. **Operations should cease entirely when MSB issues air quality alerts for high winds in the Palmer area and not resume until winds subside.**

3) Wildlife
On page 31 of the application, it states that "there is no concern of wildlife or domestic animals being attracted to the inert debris and the monofill operations. Since there will be no putrescible waste allowed (or disposed of) in the monofill, there will be no animals attracted to this site".
Migratory birds, especially water fowl, are already attracted to the ponds on the site particularly during spring migration. Plastics, styrofoam and other small debris have already been found in the water bodies and waterfowl have been observed swimming in these ponds. If the fill is placed on or near the existing ponds, it may be ingested by waterfowl with damaging results. This site is less than 1 mile from Palmer Hays Flats Refuge, the major migratory bird refuge in Southcentral Alaska, and thus will have consistently large flocks of birds (swans, cranes, geese, etc.) passing over every year. There is no plan in the application to mitigate wildlife presence, primarily waterfowl, that are attracted to this site. **A wildlife mitigation plan, particularly addressing spring migration periods, should be included in the operation plan for this permit.**

Overall, the applicant does not demonstrate an understanding of the unique water quality, wildlife migration and wind conditions that make this site challenging for their type of operation.

Dear Susan,

I have another thought. I believe that before making a final decision and taking a vote on an issue that will ultimately effect the lives and well-being of individuals and wildlife habitat in our community, now and for years to come, each member of the Matanuska-Susitna Borough Planning Commission should be asked some questions and be required to give totally honest answers. First of all, they need to imagine themselves living in the area near the gravel pit where Central Monofill Services proposes to set up their monofill operations.

The questions would be:

1. "Knowing the information and warnings that have been submitted to you regarding the risk of air pollution, ground water pollution, and wind-blown litter...as a resident and/or property owner in the area near this site, and if the monofill operations were happening, would you be willing to drink the water from your well, enjoy standing out in your yard and breathing the air, and accept the accumulation of litter on your property?"

2. "Once operations at CMS were happening would you be able to sell your home or property, once potential buyers learned of the known conditions and risks attached to purchase of your property?"

3. "If you were not a resident in this area, and were looking for property to puchase, would you consider buying property near the monofill site?"

3. "Considering all the information and warnings given; for the sake of those of us who are residents in this area and for the sake of our children and grandchildren who live here, can members of the Planning Commission, in all honesty and with a clear conscience, cast a "Yes" vote to approve Central Monofill Services being issued a permit to operate at this site?"

Thank you, Susan. I hope this email with these questions can be relayed to members of your Planning Commission before the time comes for making a final decision on this matter.

Sincerely,

Patti Goossen

Central Monofill Services (CMS) as a property owner in the Gateway Community Council would like to respond to Resolution 01-14.

CMS is disappointed that the Gateway Community Council elected to pass this resolution without providing us the opportunity to present the project at a council meeting. We understand that the proposed use of a portion of our property as a Recycle Facility and Monofill has raised concerns with members of the council and that to many people any type of Landfill has a negative stereotype. CMS recommends the Council review the CMS 2014 Conditional Use Permit application in its entirety or contact us for more details and information on the proposed project. Concerns and issues raised by the community have been addressed in detail in our 2014 Conditional Use Permit (CUP), application. We have had informational meetings for the community and have an open door policy to see our operations in efforts to help educate the community on our proposed operations. Concerns raised by neighbors over contamination and water issues led CMS to commission engineering studies by both local engineers and nationally recognized experts in the field. These subject matter experts determined our design at this location to be safe and protective of public health.

CMS has operated a similar Monofill in Salcha, Alaska since 2012. Prior to receipt of our permits for the Salcha facility we heard many of the same concerns and misconceptions from our Salcha neighbors. Today those same neighbors have firsthand knowledge of our successful operations and have written letters of support. If after a review of the application materials questions still exist we will gladly have another informational meeting for the community council.

Thank you for the consideration.

Gateway Community Council
Resolution 01-14

To: the Matanuska-Susitna Borough Planning Commission, Borough Assembly, Alaska Department of Environmental Conservation and Palmer City Council

Re: Request by Central Monofill Services, Inc. to operate a landfill for construction debris & asbestos near Mile 38.3 of the Glenn Highway near Palmer, Alaska.

A Resolution of the Gateway Community Council opposing the approval of a conditional use permit for Central Monofill Services, Inc. to operate a landfill at this location due to the threat it poses to surface, drinking and ground water and other environmental impacts,

Matanuska-Susitna Borough
Development Services
OCT 28 2014
Received

WHEREAS, the property in question is a former gravel pit previously owned by Granite Construction and is legally described as:

> 17N02E18C010 and 17N02E19B006, within Township 17 North, Range 2 East, Sections 18 and 19, and Seward Meridian; and

WHEREAS, past gravel extraction activity mined into an aquifer feeding the surrounding area, and on multiple occasions affected the water levels of surrounding lakes causing concern to property owners as well as potentially adversely affecting private wells in the area; and

WHEREAS, hydrological reports and testing by the Alaska Department of Natural Resources has indicated a connection between the aquifer on the gravel pit property and surrounding water bodies and need for more testing; and

WHEREAS, Central Monofill Services, Inc. recently bought this property for the purposes of depositing construction debris and asbestos taken from buildings in the Municipality of Anchorage and other areas; and

WHEREAS, this material poses a significant threat to air and water quality of the surrounding area; and

WHEREAS, contaminants have been found in leachate from construction and debris landfills at levels exceeding health and water quality standards that include arsenic, cadmium, lead, manganese, carcinogens such as benzene and vinyl chloride, sulfate, and also chromium and arsenate if chrominated copper arsenate-treated wood is disposed of; and

WHEREAS Central Monofill Services, Inc. has already created pollution by illegally dumping trash and ground up construction debris on said property without proper permits and with blatant disregard for the surrounding environment, groundwater, surface water and air quality; and

WHEREAS Central Monofill Services, Inc., and its manager Shane Durand were cited by the Mat-Su Borough and convicted in Palmer District Court on six counts of: violating

the borough's junk and trash ordinance, failure to comply with a borough order to clean up and operating a junk yard without a permit; and

Case Numbers:

3PA-13-03603MO
3PA-13-03604MO
3PA-13-03623MO
3PA-13-03601MO
3PA-13-03602MO
3PA-13-03624MO

WHEREAS, Central Monofill Services, Inc., has demonstrated disregard for regulations and the impacts of their activities by refusing to clean up the illegally dumped trash even after the court convictions and only removing the trash after being threatened with an enforcement order from the Alaska Department of Environmental Conservation; and

WHEREAS the residents of the Gateway Community Council and surrounding areas are concerned with the impact of the proposed monofill, and by Central Monofill Services' disregard to date for local ordinances, state regulations and the impact that their activities will have on the surface and groundwater quality, air quality and other environmental impacts; and

WHEREAS, water is one of the most valuable natural resources the MSB has, and its quality should not be compromised through short term and short-sighted economic activity that could reasonably be located elsewhere in the borough where it would not pose a threat to water quality; and,

WHEREAS, the MSB contracted an independent hydrological study and review of Central Monofill Services hydrological study with J. A. Munter Incorporated, Professional Hydrologist; and,

WHEREAS, the Munter report found that Central Monofill Services report prepared by Terrasat to be flawed in its findings and further found that the proposed Monofill poses severe threats to groundwater and downgradient wells; and,

WHEREAS, Central Monofill Services' proposed operation would generate minimal economic benefits to the borough in terms of jobs or tax revenue; and

WHEREAS, the Gateway Community Council recognizes the importance of this area and its surrounding public and private recreation areas and is proud that the Glenn Highway is a National Scenic Byway and serves as the Gateway to Palmer; and,

WHEREAS the proposed monofill is inconsistent with some of the goals and policies of the Borough-Wide Comprehensive Plan (2005 Update) and the Core Area Comprehensive Plan (2007); and

Now therefore let it be resolved that the Gateway Community Council is formally opposed to the location of Central Monofill Services, Inc. landfill at this location due to the threat it poses to surface and ground water and other environmental impacts,

Now therefore let it be further resolved that the Gateway Community Council strongly believes that the near and long-term risks are too high for this or any Monofill development to take place at this location compare to any short-termed economic benefits; and,

Signed this date

President, Gateway Community Council — Date 10-27-14

Vice President, Gateway Community Council — Date 10·27·2014

Re: Proposed Land Fill
MSB Gateway Area

It is never too late to correct a poor decision.

The negative impact of the proposed land fill will adversely affect the homes and property belonging to the residents, raising concern for the lakes and water tables of the surrounding area as well.

What impact to the Mat-Su Campus of the University of Alaska Anchorage Land Trust as bequeathed by Valley residents Fred and Sara Machetanz will threaten that large portion of the Gateway area?

Matanuska - Susitna Borough
Development Services

OCT 31 2014

Received

I am troubled by the apparent lack of concern and limited respect for the natural and unparalled beauty of our Valley, (and its residents and appreciative visitors), by the developer/s of this Land fill.

There are other sites that would be available to the developer, to utilize nearby or to develop elsewhere.

Remember, it is not too late put a more responsible direction to the growth and development of Mat-Su.

Very truly yours,

Gerry Keeling

10/31/14

To Whom it may concern:

I most strongly object to the CMS Dump project as proposed and advise the planning commission to deny the permitt application on the basis of health and safety concerns. It is completly unreasonable to propose dumping toxic waste into an open aquafir and equally unreasonable to make any statement that contaminants will not travel down gradient polluting wells and surrounding lakes. This project is totally absurd and cannot be allowed. The consequences of this will be far reaching and irreversible. We may well be looking at the greatest disaster in the history of the Mat-Su Borough. Seriously, what are these people thinking? The only logical answer to this is NO!!! Not now, not ever.

Who monitors what is dumped here?

Posted: Monday, February 24, 2014 11:59 pm

To the editor:

Most days, it smells like hydrogen sulfide outside in my yard. At least that is what the lady from the DEC said.

She came out two days after I called the Palmer Fire Department in December to investigate the extremely strong-smelling smoky odor emanating from the reclamation site that is conveniently hidden from the public view off Rebarchek Road just south of the Alaska State Fairgrounds. Today, the odor is a little stronger than normal because it is cold and there is no wind. Other days, it may be a less distinct smell, but it is constant. I know it is coming from this site because when I walk, run or ski and turn the corner by the fairgrounds, a wall of stench will sometimes hit me in the face.

I have been reassured (or have I?) that they are only dumping inert construction waste materials there. The lady at the DEC said the dump is a full 20 feet above our water table, which feeds my water well. She said that according to code, only 10 feet is required. Really? Wow, that makes me feel safe that the water table that many of us use in south Palmer is protected. But this is supposed to be inert material. Yet, it is decomposing, thus producing the constant hydrogen sulfide gas smell. My question to the city of Palmer is who monitors what is dumped there? Who monitors our drinking water? Does anyone really know how close the bottom of this old gravel pit really is to the water table? If it pollutes the air, what is all this waste doing to the ground?

I sure would be disappointed to see another dumpsite be located in south Palmer. Sure, Central Monofill Services may have all the answers regarding groundwater contamination and blowing debris, but what if they are wrong or under estimated? They are dumping waste and it will decompose to some degree over time. It will be there a long time, causing odors, possibly contaminating the soil, water and making permanent changes. Please let your voices be heard to the Mat-Su Borough Assembly members, planning commission and city of Palmer before we have another stinky unpredictable site on our hands.

Teresa Beck

NOV 03 2014

Re[illegible]

October 31, 2014

Dear Susan Lee,

This is an add-on to my previous comments, dated October 30, 2014 FAXed to you.

Central Monofill Services claims their monofill set-up and processing system would be environmentally "safe". Since it is a man-made set-up it is impossible to make even the everyday operations 100% safe. No system involving so many variables in management, ground exposure, weather, and unforeseen "acts of nature" can claim to have no risk of damages to the environment. I feel that the bottom line in this whole matter with the proposed monofill site is that there are no guarantees that the environment would not be harmed. Is it truly worth putting the health and future well-being of humans at risk?

Sincerely,

Patricia Kepler Goossen

NOV 0 3 2014

Received

Dear MatSu Governing Officials:

I am sending this by fax, as my email was not going through. I hope you will still accept my comments in light of the difficulty with the internet connection or server.

I am writing because I am very concerned about the CMS plan to install a mono-fill dump on land that is very close to my home. It is very unfortunate that better protections are not already in place to prevent this from happening. We, as a community, need to decide what is best for our area. As our representatives, I hope you will listen to all the people who have spoken on this issue. Really, a corporation is a single entity under the law, and should not carry more weight than the opinions of thousands in the community.

The proposed mono-fill would be placed in an area where a previous gravel pit disturbed the aquifer. The company even admits that a portion of this property does not have adequate separation from the aquifer. They plan to push some gravel into the area to a get a minimum separation. However, there are many surrounding homes directly tied in with the aquifer, and use this water directly for drinking purposes. Several people reported well changes when the gravel company originally penetrated the aquifer. Please understand that the land fill contents will not be 'inert' or non-toxic. You have seen the products proposed, including asbestos. Other products are also very dangerous. They would place ground up pressure treated wood, which leaches toxins such as arsenic into the water for many years. This is just to name a couple. I have studied the science behind it. A few feet of gravel will not prevent the groundwater from becoming contaminated.

The CMS company wants to put asbestos on this property. We all know of the high winds that bring continual erosion to the landscape. At some point, we will likely have high winds blowing the asbestos particles into our air. Who will take on the liability for the resulting asbestosis lung disease?

Please also consider the big picture. This is a shell corporation that will have limited liability. They plan to bring Anchorage waste to the Valley, bypassing a dump, so they can save on disposal fees, and thus make more profits. They would make these profits at a great risk to residents of the Palmer area. We feel Anchorage should deal with its own trash, and not put it into our community -especially not into a residential area.

Consider this companies track record. They have already been cited for breaking our laws. Consider that they want to monitor for contamination themselves. Talk about a conflict of interest! There would be no third part government monitor. They have not even addressed our concerns with a change in plans, but are just banging on the door, trying to ram it through again.

I know many write off our opinions, because no one wants a dump near their house. However, there are many other places where this dump could be installed. Perhaps, some place where the aquifer has not already been penetrated, some place not so exposed to high wind, some place not directly next to our homes.

Matanuska - Susitna Borough
Development Services

Received

Matanuska - Susitna Borough
Development Services

I fear that in the future, the Mat-Su will be exposed to multi-million dollar lawsuits, for groundwater contamination, loss of groundwater rights, lung diseases, and more. This has happened all over the country when local governments failed to protect the citizens.

You are in charge of planning. You are in your positions to serve our community. Please do not put the desires of a single entity above the safety, community will, and future direction of our fine borough.

Sincerely,

Christopher Sahlstrom, MD

Subject: monofill CUP

10/31/14

To Matsu Borough Planning,

I am writing this letter in support of Central Monofill Services' application to permit a C&D monofill. As a resident of the Matsu, I understand and appreciate the Borough's apprehension in approving the CUP in 2013. After reviewing the current application though, it is abundantly clear that CMS has taken the feedback and concerns raised by the Planning Commission and neighbors, and through clarification and added studies, has proven that their operation is environmentally responsible, safe, and an asset to the Matsu Borough as a whole. The numerous benefits this facility will provide to the communities of the Matsu are well documented within the application material. A recent flier circulated by the opposition to this project asks "could there be a worse location". Now that CMS has proven that leachate and ground water contamination concerns are unfounded, Could there be a better location?, seems to be the more appropriate question. The central location, heavy industrial use of surrounding properties, highway access, lack of direct line of sight to the fill operations, and the fact that this type of industrial usage is exactly what the MSB Comprehensive Plan seeks to encourage at mined out gravel extraction sites, makes this location ideal. The MSB already has enforceable codes in place to address windblown debris leaving the property. Denying the CUP based on this concern is illogical. Allow CMS the opportunity "to be innocent until proven guilty", their application demonstrates that they recognize the risk, and have an adaptive plan in place to deal with the wind.

I urge the MSB Planning Commission to look past the vocal opposition, who seem to be willing to make any argument to stop this project, and the negative stereotypes associated with traditional landfills, and vote to approve the CUP. Please do not allow NIMBY to stop this project and the progress of recycling, especially unsubsidized recycling, in the Matsu and Alaska.

Sincerely,

Wes Walling

Letter of Support for Central Recycling Services and Central Monofill Services Project

Calbag Metals has been in the recycling industries for over one hundred years. We are an ISO 140001 certified facility and as environmental stewards, we work very diligently with our suppliers to insure that they also handle materials and material processing in a manner that is responsible. Central Recycling has sent employees to observe and train at our certified facility and other long standing reputable yards. Recycling materials that would otherwise end in land filling is the responsible and environmentally conducive to insuring quality of life issues for the future. The materials being recycled also require less energy, water, and other natural resources. Central Monofill Services will expand the recycling services that will not only be environmentally responsible but will stimulate local economy and tax revenue that will enhance many other programs. We support CRS and CMS in their expansion endeavor.

Subject: Palmer toxic dump

We write this letter as community members for over 30 years, we have raised our family in this valley and watched as our son grew to become a man in this community. We also write this as an apology to those future sons and daughters who will not have what our own son had, a chance at being free and enjoying our great land. Somewhere along the line in our community we forgot about the ties that bind us together and make us a community and we started to look out for making a quick buck and now the devil wants his due. Everyone always said the valley was big, but after a while after seeing test wells being forced into people's backyards and gravel pits slowly growing to devour the wild places where a person could hike or hunt, we feel a chill in our bones. The valley is a place of wonders with green hills and breathtaking sights, but over the years special interests and representatives have tried to sell the soul of our community, its natural abundance and splendor, which greeted us each day. Could the Founding Fathers of Manhattan ever have imagined that their splendor would be spent so quickly and be lost for a dozen generations even quicker when they greeted each new day? We took for granted and never could believe that the waste and filth of others would be greeted so greedily and lovingly brought into our community. A few pieces of papers and some shiny metal coins for the loss of our land for generations seems like a sad trade, but it seems the devil gets what the devil pays for. Long after the outsiders who dumped their poison onto our lands have gone and the quick buck made has turned to dust another more sinister dust will remain to blow across someone else's brow who will be sitting and looking at the remnants of the filth and trying to explain to a child the cost we paid to take poisons into our bodies every time we take a sip of water or eat a fish caught in some local stream or the hint of some unnatural things in the wind and why we sacrificed the place where we lived for some paper script. They say we did not speak up, they say we did not stand up against the loss of our land, even if that is true for some it is not true for all. For their will always be those who will say no even when it's not fashionable to say no. We say no, there are some prices to high to pay and for those future generations being robbed before they are born, we mourn for what you have lost before you ever knew it.

Subject: Re-application by Central Monofill Services, Inc. For CUP

Susan Lee of the Matanuska-Susitna Borough Planning Commission,

In regards to the proposed Monofill by Central Monofill Services, Inc., it is, simply put, one the absolute worst type of businesses to be built on that particular property. These monofills have a history of leaking toxins into the air and water systems in several locations in the Lower 48. Ohio is currently dealing with this very issue in the majority of their monofills, and are currently working on creating regulations- after the contamination started. After the fact is too late. The health and safety of the people there and here is being threatened through water contamination and through the air in the way of toxic fumes, (such as Hydrogen Sulfide & others), and through wind blown debris as nearby residents experienced last year when high winds scattered CMS's illegally dumped garbage all over their yards. There have been 2 major hydrologic studies done: one in the past & another done recently by the same expert- Mr. Munter, that discuss the water issues in depth. The aquifer breach by the gravel company that owned the land previously directly affected the levels of nearby lakes and a multitude of private wells. That demonstrates a precedent of water issues long before CMS came along. Combine the major water issues with dumping construction debris to include asbestos, treated lumber etc, into holes in the ground with no impermeable liners, and no regulation or oversight, and you have a recipe for certain disaster.
I am not opposed to economic growth, unless it comes at the expense of the people and the resources they rely on to live. You have our health and resources in your hands, we are counting on you- please protect us.

Sincerely, Roy Kallander, Jr.

Subject: Central Recycling Services Monofill Permit

Dear Ms. Lee

I would like add my comments for the support of the proposed land fill development of Central Recycling Services. This is a much needed monofill that currently does not exist in the Valley. Failure to develop this type of facility is a huge mistake. We need to recycle building materials and conserve our resources which cuts costs and certainly reduces the amount of waste going into the Borough land fill. As the population grows the demand on our Borough infrastructure is growing and the need to use every means of keeping down the filling of our land fill is critical. The proposal will allow for the recycling of construction wastes and reduces waste. It appears just down Pittman Road from me the old saloon on the corner of Pittman & the Parks Highway is about to be taken down. i imagine this facility would make it possible to recycle much of that wood but without the proposed it will be dumped never to be used again in the Borough land fill.

Please support this application for permit.

Subject: Please support the Central Monofill Services Conditional use permit

To whom it may concern:

I am a Fairbanks resident and I grew up in Salcha Alaska where Central Monofill recently opened a new site that has been operating for several years now.

Not only is the facility run very clean and in a business like manner but they have actually upgraded the land that was previously a junk yard and hazardous to the neighbors. The property has actual curb appeal now and Central Monofill along with being a reputable business is a very good neighbor to the residents in the area. Central Monofill has spent an incredible amount of time and effort to not only minimize any impact to the area but also to improve roads and to some extent the quality of life for their neighbors.

We of course had some reservations due to our lack of knowledge on the subject, but after reviewing the plans and talking to the owners and operators of the facility we came to understand the importance of the service to the community and that it did not have to come at a price to the locals.

As this is the same company that is looking to open in the Matsu area I not only support them but think that we would be negligent in stopping one of our local Alaskan companies from keeping "our" Alaska clean and tidy.

Please do not let fear and propaganda dictate the growth and development of our great state!

Sean Holland

Hi Susan

Please find Mt. View Estates HOA comments concerning the Conditional use permit for the operation of a monofill for CMS attached to this email.
Thank you for considering our comments

On a side note I have never understood how the initial conditional use permitting for this property with the previous owner was not binding by law regardless of transfer of deed.

Thank you
Emmett Leffel

Memorandum

Date:	October 2, 2014
From:	Susan Lee, Planner 11
Subject:	REQUEST FOR REVIEW AND COMMENTS
Project:	Application for a conditional use permit for the operation of a monofill
Parcel ID:	Township 17 North, Range 2 East, Sections 18 & 19, Seward Meridian
Applicant:	Central Monofill Services

Thank you for receiving and considering our comments concerning these important issues. It is with great concern that we as a Home Owners Association respond to this memorandum. Our earlier testimony on these issues pertaining to this applicant and conditional use permit has been recorded and heard by the Borough concerning this Applicant's failure to meet reasonable expectations of the Borough and its residence. This applicant has proven from day one that they are not concerned with protecting our water quality, land, air or even following basic permit guidelines and requirements. The gross violations of their previous conditional use permit and blatant degradation to surrounding environments and water quality has proven their complete disregard for community and our environment. Mt. View Estates HOA's primary concern is protecting our quality of life, property value and our water supply. With a community well serving our entire subdivision connected to the same aquifer that has been punctured on this property, we strongly urge the Panning Division, the Borough Manager and Assembly to reject this permit application for the operation of a monofill.

Respectfully

10-30-14

Subject: CMS Conditional use permit

As a lifelong Alaska resident and a Palmer resident in the Matsu Valley for 14 years I am in support of Central Mono fill services conditional use permit . I believe it will bring jobs to the valley and bring a much needed service in construction debris recycling and disposal industry to the valley.
CMS has proven they can do this responsibly with their operations in Fairbanks at the Salcha mono fill .
And I believe they can do it in the same responsible manner here in Palmer Alaska.
Please support the responsible disposal of construction debris and recycling in Alaska Paul Weir

Subject: Comment on proposed mono fill

Please don't allow this environmental nightmare to occur! I am not just saying this because my living room windows look right down into the center of it, but because Alaska should put the hard lessons of the lower 48 to use. We have already been subject to big companies that move in, create an ecological mess, change the company name, and hide behind a paper trail of company sell off's. We have already seen it in action with the so-called gravel "pit". The original mine operator filed a reclamation plan that kept the local population and governing body happy and as soon as they took the easy money, sold the property and made the dredge ponds somebody else's problem leaving the local population with an eyesore and having to deal with it. This also leaves the local government with endless and costly lawsuits as well as having to clean up a business's mess. Apparently no one is holding these companies responsible for their actions . All of this expense heaped on to the tax payers of the Borough just for some short-term profit. Have we not seen enough damage from toxic runoff from tires. Tires are not an inert material and please show me a building in alaska built from tires which are a petroleum product. So much for a mono-fill. The toxic runoff from alone will be enough to render the entire area useless for future development since it will be too unstable to build on in earthquake country. All you have to do is look at the h hills bordering my property to see the erosion that will take place from wind and water. With no plan in place to monitor and inspect each load this monofill will become just another land fill and set a precedence for future such projects.

If the borough is looking at income from sales tax and a few jobs they are not seeing even a small piece of the big picture. Property values in the area have already been projected to fall at least 15%, so begin the lawsuits if the borough doesn't lower property taxes in the area willingly and up front. Once CMS is done with this project the entire area is lost square footage to future tax revenue and the borough is stuck maintaining and monitoring forever, the loses just keep piling up just so one man can reap profits. The loss of property value cannot even be calculated. No one wants to move into an area that is essentially a giant open pit mine that will eventually become an enormous land fill. The original reclamation plan for high-end housing around a recreational lake with easy commute to Anchorage and the base's would bring long term growth and revenue to the Palmer area as well as high paying construction jobs in the short term.

I also believe the State and CMS are missing an opportunity on railroad property across the highway. There is a gravel pit with easy access to a rail spur which could cut transportation costs and have access to gravel resources.

Subject: landfill - Central Monofill Services

I am writing to voice my family's opposition to the landfill proposed by Central Monofill Services. The proximity of this landfill to lakes and residences is worrying. Most homes in this area rely on individual wells for their water supply. Many people use the lakes for recreational pursuits, with a positive economic impact. Risking the aforementioned for short term economic gain does not seem to be in the best interest of area residents. The Palmer area is a wonderful, unique place. Surely there are less destructive avenues to pursue for economic growth.

Thank You and Best Regards.

Subject: Comment on the Proposed Monofil Site Conditional Use Permit

Importance: High

To: Ms. Susan Lee, Mat-Su Borough.

There is an open comment period that closes at 0500p on October 31, 2014 for a proposed monofil site on the Glenn Highway in the unincorporated limits of Palmer, Alaska. At first glance this proposal appears somewhat inert, however, on the basis of the anticipated site material, specifically:

Regulated Asbestos Containing Material (RACM) and Non-RACM will be accepted at the site.

Location:

The proposed site is located on MSB Tax Parcels: 17N02E18C010 (2840 S. Glenn Highway) and 17N02E19B006 (2560 S. Glenn Highway); within Township 17 North, Range 2 East, Sections 18 and 19, Seward Meridian

This issue deserves a closer look. Living at 7000 E Lower Mesa Drive, Palmer, approximately three miles due west of the proposed monofil site, I have the following comments:

1. A ten foot designated separation to an unlined dump site for known hazardous materials (asbestos) from an aquifer water table used by thousands of people is potentially criminal – individuals should review such cases as the Lynn Canal – and I have water rights for my well as do many others – with no public water supply.
2. This area, in which I have resided for over thirty years, experiences from three to six wind events per year where winds in excess of sixty mph from the east/southeast create an extended dust plume from the gravel pit in question and others in its immediate vicinity that extends far beyond my residence does not need to be supplemented by known hazardous and carcinogous materials intentionally dumped at the proposed location merely for convenience or individual economic gain. It should be noted that this dust plume encompasses a regional hospital, a State College, an elementary school, and hundreds of homes and dozens of businesses.
3. If a permit is granted then the permittee should be required to bond against any and all health issues generated by this site for the potential time frame within which the site represents a potential hazard to both the aquifer and the downwind atmospheric volume where hazardous material dust may be propagated. A reasonable wind event should be determined (maximum observed by me to date is approximately 110 knots) and a legitimate wind impact zone determined to evaluate the true impact of such a material release on those community elements stated in item #2. above.

I am available to discuss any aspect of this comment should you chose to do so. Thank you for this opportunity.

David Palmer

Subject: Public Comment for Planning Commission

Mat-Su Borough Planning
Attn: Susan Lee
slee@matsugov.us
Public Comment to Planning Commission

Dear Planning Commission

We live on Canoe Lake and are opposed to Central Monofil's permit for a private dump at mile 38.3 of the Glenn Hwy.
This dump presents threats and hazards to the local surrounding area: Health, drinking water, lakes, fish, environment, natural habitat, wild life, air quality, and devastating results in the event of an earth quake or fire. It will be an eye sore, reduce property values in the region, and will be a detriment to our otherwise pristine national scenic byway.

Water quality is vital: It is the worst location for a monofil in the whole Matanuska/Susitna Valley because the site sits on top of the massive aquifer that feeds our lakes and provides drinking water. People with wells that are connected to the aquifer will not have confidence in drinking the water that once had no threat of pollution. The aquifer is connected to the water that feeds the surrounding lakes. The Kepler/Bradley Lake Systems and and Matanuska Lake Recreation area will be under threat of irreversible contamination. Local residents and tourists alike enjoy fishing in the pristine unpolluted waters in the rivers and lakes in the close surrounding area. With the threat of the dump that could contaminate the lakes it will detour recreational fishing in the area. When the lakes are contaminated it will pollute and possibly wipe out our fragile eco system and kill fish, waterfowl, birds of prey and wild life that live around and in the lakes. We have nesting eagles and osprey who hunt in this region. Central Monofill has not regulated the water levels in the ponds in order to protect the water levels in the surrounding lakes. How can we trust that they will protect the water quality?

. A dump permit would allow tanks and potentially leaky equipment to be parked next to the ponds open to the aquifer. Accidents happen. The aquifer is only 2 feet below the surface and even if they state there is 10 feet, how can microscopic pollutants be filtered out in just 10 feet, Even if they line the dumping cells, they will have to pump them out – who will regulate this procedure to protect any spillage into the ponds or grounds. Where will they dump this toxic fluid?

ASBESTOS, HEALTH CONCERNS:, Cancer from asbestos is life threatening! Who will monitor the owners to make sure they dump the asbestos safely. Those who live close by are asked to take a drastic health risk and trust our lives and in the professional credibility of the monofill owners and staff. They to date have already been sited for not complying with contracts and codes. How can they be trusted? It will be cost prohibitive to pay borough staff to their monitor dumping practices, so they will be dumping without accountability and monitoring. Accidents happen and the local residents will suffer irreversible health issues as a result.

The dump is in a wind tunnel that can get winds up to 80 mph that snaps trees and tears roofs off of houses and causes substantial damage to structures. These winds will blow any trash that has not been covered adequately, and blow not only trash but air pollutants causing health hazards. It will harm those with lung issues such as asthma, emphysema etc.

CMS also wants to store and sell salvaged items and materials and vehicles & who knows what else? There will be stacks of vehicles, and junk that may also leak and pollute. Do we want a "Sanford & Son's" junkyard at our gateway and along our scenic byway, and down the highway from our new visitor center! This will be a detriment to our image and make us live up to the name of Valley Trash. We will be a joke and Anchorage will be laughing as we store and dump there trash in our front door!!

The borough would make so much revenue if they had to pay to dump in borough dumps. What is the reasoning that would cause the borough to let them create an eye sore and health hazard when they could be making money from these folks. If they want to bring Anchorage trash here they should pay like everyone else!!!

What happens WHEN there is an earthquake? The 64 earthquakes damaged our wetlands and rocked this area too!!! We have had some significant earthquakes in the last few months in the valley. I live just blocks away from the dump and our house was rocking and shaking.

The monofill site was supposed to have been developed into a beautiful subdivision for lakefront homes. There was only one problem… The soil in this earthquake zone is too unstable for building. The sand will liquefy in an earthquake. It may also subside as the hay flats did during the 1964 earthquake.

The CMS site is too unstable to support a house, but it is being planned to support a chemical containing waste pile 8 stories high. With the groundwater at ground level currently and many earthquakes to come, we could easily end up with a site that has acres of waste continuously leaching directly into groundwater.

What if there is a wild fire?? The toxic garbage and tires will heavily pollute the air and environment.

This is a "NO BRAINER" anyone who votes r to approve the CMS dump application is either mentally unstable or "bought off" by CMS – in either case they should be removed from the Planning Commission. The community is watching and trusting the Planning Commission to make a decision on what is best for the communities health and well being and image. Will the Planning Commission vote for what is best for Valley residents or for questionable a Anchorage business.

We support the plan that was created and approved by the community which preserves this area for a a beautiful park or something that will benefit our community and compliment our National Scenic Byway, and be a beautiful welcome to our Valley that is just up from our new visitors center.

Sincerely
Geri McCann

Subject: Comment for submission about Monofill in Palmer
Attachments: Honorable submit.doc

Dear Susan Lee,
First of all I would like to offer you my sympathy on being the contact person on such a sensitive topic. I have attached my letter that I would like to submit on the Central Monofill Services Dumpsite permit in Palmer. I have also pasted the letter below incase you cannot open the attachment for any reason, you may use either letter since they are the same. Please email me a verification that my letter will be submitted with the public comments on this permit. Please email me if you need me to send it again or have any questions.
Thank you and I hope you have a Happy Halloween and a great weekend,
Rebecca Jeffers

Honorable Matanuska-Susitna Borough Planning Commission members,

My parents and I own a home and live on Canoe Lake in the Bradley – Kepler subdivision. I am writing to express my concern over the purposed conditional use permit for the operation of a monofill for the disposal of non-asbestos material and asbestos material located on parcel #17N02E18C010 (2840 Sl. Glenn Highway) and 174N02E19B006 (2560 S. Glenn Highway). It is my concern (and all of our neighbors) that this landfill will taint our underground water reservoir that supplies all the wells and lakes in and around that area. The lakes (Irene, Canoe, Bradley, Long, Kepler, Matanuska lakes) are stocked with fish by Fish and Game. Also, many people come to these lakes to swim and others come to fish and then eat the fish which they catch. My neighbors and I around these lakes are on well water, thus alarmed at the situation we are put in, to make sure nothing is started or completed around us that will contaminate our only water supply.

The parcels that Central Monofill wants to have a dump on have been problematic for years. Furthermore, the aquifer in those parcels has also been problematic for many years since the gravel pit punctured it. The gravel pit reassured the residents around the incident with promises that the area would be reclaimed once it was no longer an active gravel pit. Many of us residents even submitted different reclaiming ideas and there were many people willing to volunteer time and trades to assist the project. One idea was to turn it into a park, with 2 ponds, some barbeque grills and picnic tables. Maybe even have a nice soccer field for the local teams to play on. We could even dedicate and name it after a prominent Palmer or Alaska leader.

It is my concern that putting in this monfil site will decrease the property values around it. These decreases in values have been verified by multiple real estate agents for the Matanuska Susitna Valley. If the values of the properties decrease, so does the security of those families. In addition, a monofill site will bring more noise, odor, and traffic which will be incredibly upsetting to an area that is use to clean, beautiful and serene surroundings.

Central Monofill Services has no long term plans on protecting our water, nor do they have any monitoring plans for the water pollution or air pollution that is probable to occur. Also, they have plans for putting in a fence or tire bails, but not for covering it to keep the fly away debris to a minimum; thus creating a messy subdivision behind it and roadway in front of it, given that the winds will blow debris into both the subdivision

and the roadway (consequently creating a driving hazard). The wind here swirls creating a tornado like scenario and the proposed tire bails and fences will not catch any of the debris whirled up by the vortex. What is the plan for picking up the debris that gets out of the monofill site and how are they going to deal with the high winds that we get here which can last more than five days? Debris may well end up in the stocked fishing lakes too. How will this affect the farms around us, our pets and our children? Will we end up with contaminated food? This is not an appropriate location for a Monofill dumpsite.

Our State Representatives, Borough Assembly Members, Borough Mayor and Planning Boards are the public's first line of defense. Thus, they need to be ethical and good stewards for our communities and environment. One fix would be for the Borough Assembly and Mayor to adopt the Anchorage Codes for zoning and permitting. These codes would prevent Central Monofill Services from putting this type of a dump in a residential area. The Matanuska Susitna Borough could tweak the codes in the future if they need to, but this would give the residents and community protection immediately.

You have continually been sensitive to the protection of the Palmer culture and atmosphere. You have also been marvelous in understanding the family character and strength of our neighborhoods and community. I am hoping and urging you to heed the concern, and fear, the people of Palmer now face. Help us safeguard our community (and farms) for the countless generations we know will live in this subdivision and community. Not to mention the innumerable number of people that will come to these lakes for recreational delight. A residential and sport fishing area is assuredly not the location for a waste dump which will contain hazardous materials. This dump "will" contain regulated and non regulated asbestos materials per the letter received from the Matanuska-Susitna Borough Planning and Land Use Commission. Non-regulated asbestos requires full hazardous material suits and respirators when working around it, yet the ground (which is only 10 feet above an aquifer that is the only supply of well water for multiple subdivisions) will not even have a liner! The company Central Monofill Services has many alternative locations more appropriate than this from which to choose. In the short time this company has been around they have already amassed violations, fines and even had to have the DEC provide them with a cease and desist order so they would stop dumping in the Palmer location that they did not have a permit for! That site is the same site in Palmer that is being applied for again! Furthermore, they are currently in Court in Anchorage for Violations! This, in itself, is not reassuring. (Please see the Facebook page 'Palmer Toxic Dumping' for more information about how the community feels on this issue). This is not a suitable location for a Monofill dumpsite.

Please say NO to this Monofill site for your future, and the future of the generations yet to come. Many people have talked against it and then when the time comes they voted to approve it! This makes the tax payers wonder how much they were paid for their vote. Will you be a voice against the asbestos containing Monofill for the residents of the city you in charge of? If these parcels need to be turned into something then ask the community for ideas (like a park) and volunteers; the community will come together to make it happen. The community supports a park and intensely opposes a Monofill dump.

Central Monofill Services are technically not a Monofill since they will have non asbestos material, regulated asbestos material and non-regulated asbestos material – a Monofill is called that because they only dump a single type of material – normally inert non asbestos containing material. This means Central Monofill Services is not even staying true to their name.

Central Monofill Services tried last year to get a dump permit for the same location that they are applying for now and they got told NO! All of the Palmer residents, Real Estate agents, lawyers and community councils who attended the meeting were against the dump! The only people for the dump were on their payroll! Please help us protect our futures and the futures of our children.

Let's all stand together and STAND AGAINST Central Monofill Services' asbestos dump site in Palmer.

Sincerely,
Rebecca A. Jeffers, 2360 S. Killarney Drive

ASBESTOS, HEALTH CONCERNS:, Cancer from asbestos is life threatening! Who will monitor the owners to make sure they dump the asbestos safely. Those who live close by are asked to take a drastic health risk and trust our lives and in the professional credibility of the monofill owners and staff. They to date have already been sited for not complying with contracts and codes. How can they be trusted? It will be cost prohibitive to pay borough staff to their monitor dumping practices, so they will be dumping without accountability and monitoring. Accidents happen and the local residents will suffer irreversible health issues as a result.

The dump is in a wind tunnel that can get winds up to 80 mph that snaps trees and tears roofs off of houses and causes substantial damage to structures. These winds will blow any trash that has not been covered adequately, and blow not only trash but air pollutants causing health hazards. It will harm those with lung issues such as asthma, emphysema etc.

CMS also wants to store and sell salvaged items and materials and vehicles & who knows what else? There will be stacks of vehicles, and junk that may also leak and pollute. Do we want a "Sanford & Son's" junkyard at our gateway and along our scenic byway, and down the highway from our new visitor center! This will be a detriment to our image and make us live up to the name of Valley Trash. We will be a joke and Anchorage will be laughing as we store and dump there trash in our front door!!

The borough would make so much revenue if they had to pay to dump in borough dumps. What is the reasoning that would cause the borough to let them create an eye sore and health hazard when they could be making money from these folks. If they want to bring Anchorage trash here they should pay like everyone else!!!

What happens WHEN there is an earthquake? The 64 earthquakes damaged our wetlands and rocked this area too!!! We have had some significant earthquakes in the last few months in the valley. I live just blocks away from the dump and our house was rocking and shaking.

The monofill site was supposed to have been developed into a beautiful subdivision for lakefront homes. There was only one problem… The soil in this earthquake zone is too

unstable for building. The sand will liquefy in an earthquake. It may also subside as the hay flats did during the 1964 earthquake.

The CMS site is too unstable to support a house, but it is being planned to support a chemical containing waste pile 8 stories high. With the groundwater at ground level currently and many earthquakes to come, we could easily end up with a site that has acres of waste continuously leaching directly into groundwater.

What if there is a wild fire?? The toxic garbage and tires will heavily pollute the air and environment.

This is a "NO BRAINER" anyone who votes r to approve the CMS dump application is either mentally unstable or "bought off" by CMS – in either case they should be removed from the Planning Commission. The community is watching and trusting the Planning Commission to make a decision on what is best for the communities health and well being and image. Will the Planning Commission vote for what is best for Valley residents or for questionable a Anchorage business.

We support the plan that was created and approved by the community which preserves this area for a a beautiful park or something that will benefit our community and compliment our National Scenic Byway, and be a beautiful welcome to our Valley that is just up from our new visitors center.

Sincerely

Kevin McCann

Subject: Objection to Central Monofill Services, Inc. Conditional Use Permit

Susan Lee, and Matanuska-Susitna Borough Planning Commission,

The application for a Conditional Use Permit by CMS, Central Monfill Services, Inc. for building and operating a Monofill at Milepost 38.3 of the Glenn Highway poses a direct threat to the population's health and safety. With a system of lakes, over 50 private wells and an aquifer that has millions of gallons of water flowing through it makes this property one of the worst areas anyone could place a unlined, unregulated asbestos and construction debris dump! The environmental threat is not limited to the water supply, but to the air as well. High winds common to the Region scatter debris, as the surrounding neighbors found out after CMS illegally dumped garbage last year. Those same winds would scatter any airborn toxins as well. The damage caused would be uncontainable and far too expensive for CMS's woefully inadequate insurance policy to cover. Currently the state of Ohio is drafting regulations now that 29 of 30 Monofills there are leaking 7+ toxins into the ground at levels exceeding health standards. Many other states have Hydrogen Sulfide gases leaking into the air from their Monofills. After reading CMS's proposal and the hydrologic reports from both sides, there are no adequate plans to contain and protect

A main reason for granting Conditional Use Permits is for economic development. What are the economic benefits to the Valley with this privately owned and operated business that pays little more in property taxes than a single-use residential home in the area and that will employ only 3 full-time employees? They will escape Anchorage's higher Municipal dumping fees and will likely divert money away from the Central Landfill. CMS will reap all of the financial benefits while Palmer and everyone downstream and downwind will reap all of the consequences, not a fair trade any way that you look at it. The City of Palmer doesn't like the idea either and just drafted a resolution against it. This type of business also conflicts with aspects of the Borough's Comprehensive Plans.

I haven't even addressed the impact to traffic on the Glenn Highway with year round operations estimating up to 100 trucks a day during the peak months of Spring and Summer. The large number of drivers that commute to Anchorage, which includes my husband, as well as tourists and all other motorists will all be directly impacted by this. There are so many other locations in the Valley that could be appropriate for a Monofill, the property at Milepost 38.3 of the Glenn Highway is absolutely the most inappropriate site imagineable for a Monofill. After reviewing all of the facts, I pray that the Planning Commission acts to protect the public from this very real threat.

Thank you, Lisa Kallander, 3185 S Lakeshore Loop, Palmer.

To: Susan Lee
Subject: Central Monofill Services, Inc.'s Conditional Use Permit Application

To Susan Lee and Matanuska-Susitna Borough Planning Commission,

Milepost 38.3 of the Glenn Highway, the site CMS, Central Monofill Services, Inc., wants to build and operate a Monofill, a business which in this location, would pose a direct threat to the population's health and safety. With the nearby system of several lakes, over 50 private wells, and an aquifer that has several millions of gallons of water flowing through it is one of the absolute worst locations anyone could place an unlined and unregulated asbestos and construction debris dump. Hydrologic studies have shown that the water table is very close to the surface, and it's levels unpredictable. This was discovered when the gravel company that owned it prior to CMS breached the aquifer and caused nearby lake levels and private wells to be altered. This set a precedent for water issues on this site. The environmental threat is not limited to the water supply but to the air as well, as homeowners nearby discovered after CMS illegally dumped trash and high winds common to the Region scattered the garbage all over their properties. Those same winds would distribute any toxic gases such as Hydrogen Sulfide which has been found leaking into the air from Monofills in other states. Ohio is currently drafting regulations after 29 of 30 of their Monofills have been leaking at least 7 toxins at levels exceeding safety standards. Once these toxins have leaked, total containment and cleanup are difficult if not impossible, and the associated costs are astronomical. CMS's woefully inadequate insurance policies wouldn't be able to cover even part of it.

A main reasons for a Conditional Use Permits is to promote economic development, but where is the benefit to the Valley when a privately owned business that pays slightly more property taxes than a single family residence in the same area plans to hire only 3 full time employees? The company will also gain relief from Anchorage's higher Municipal dumping fees and will divert money from the Valley's Central Landfill. They reap all of the benefits while the Valley reaps all of the consequences, not a fair trade any way you look at it.

The Glenn Highway will also be affected greatly by the year-round operation, especially in the peak Spring and Summer months with up to 100 trucks a day. The numerous Anchorage commuters, which includes my husband, the tourists, and all other drivers will definitely be impacted.

There are several locations in the Valley that could be appropriate for a business like this. MilePost 38.3 of the Glenn Highway is the least appropriate site imaginable. The facts show without a doubt that a different location is the only solution, I hope that the Planning Commission once again has the wisdom to see this and to continue to protect us because you have our health and safety in your hands.

Thank you, Lisa Kallander, 3185 S Lakeshore Loop, Palmer

The Matanuska-Susitna Borough Planning Commission will consider the following:
Application or Item: *Application for a conditional use permit for the operation of a monofill for the disposal of inert material*
Matanuska-Susitna Borough Code Section: MSB 17.60 – Conditional Uses
Applicant: Central Monofill Services
Request: *An application has been submitted for the operation of a monofill for the disposal of inert material. The inert debris wil primarily be non-hazardous shredded residual, non-recyclable waste material from construction and demolition waste Regulation Asbestos Containing Material (RACM) and Non-RACM will also be accepted at the monofill site.*
Location: MSB Tax Parcel# 17N02E18C010 (2840 S. Glenn Hwy.) and 17N02E19B006 (2560 S. Glenn Hwy.); within Township 1' North, Range 2 East, Sections 18 & 19, Seward Meridian.

The Planning Commission will conduct a public hearing in the Borough Assembly Chambers, Palmer, Alaska, on this item on ***December 1, 2014*** The meeting begins at 6:00 p.m. ***Public hearings begin at 6:15 p.m.*** This may be the only presentation of this item before the Planning Commission and you are invited to attend.

This conditional use permit application will be introduced for public hearing at the **November 3, 2014** Planning Commission meeting. The Planning Commission members may submit questions to the Planning Commission Clerk concerning the matter or request for more information from the applicant at the time of the introduction. All questions and requests submitted by the Commission shall be in writing and copies will be provided to the applicant and made available to all interested parties and the public upon request. Answers to questions and additional materia requests will be addressed in the staff report for the public hearing.

Commission members may not receive or engage in ex-parte contact with the applicant, other parties interested in the application, or members o the public concerning the application or issues presented in the application.

Application material may be viewed on-line at www.matsugov.us and clicking on 'Public Notices'. Application material may also be reviewed i the Borough Permit Center. If you have any questions or, would like to send us comments, concerning the proposed action, this form may be use for your convenience by filling in the information below and mailing it to the Matanuska-Susitna Borough, Development Services Divisior Planning Department, 350 East Dahlia, Palmer, Alaska 99645. You may fax comments to 861-7876 or e-mail to *slee@matsugov.us*. For additiona information please contact Susan Lee, Planner II, at 861-7862. Comments received by ***5 p.m., October 31, 2014*** will be included in the Plannin Commission packet for the Commissioner's review and information. Please be advised that comments received from the public after that date wi not be included in the staff report to the Planning Commission but will be provided as hand-outs to the Commission. If there is not enough roor below, please attach this sheet to another piece of paper. **In order to be eligible to file an appeal from a decision of the Planning Commission, person must be designated an *interested party*. See MSB 15.39.010 for definition of "*Interested Party*". The procedures governing appeals t the Board of Adjustment and Appeals are contained in MSB 15.39.010-250, which is available on the Borough internet home page (http://www.matsugov.us), in the Borough Clerk's office, or at various libraries within the borough.**

Comments: Clearly, The only reason CMS wants to haul Anchorage trash to The Valley is to save themselves money. Anchorage has a dump of its own. The valley has two existing monofills. If we are going t accept out of town trash lets get the same rate as the Anchor dump gets for out of town trash - Twice the local rate. Let CMS bring it to the MSB C+D Pit. The proposed area is a damaged and fragile watershed.

Comments: Why would anyone consider letting waste material and runoff flow into a body of water being fed year round from a punctured aquafard. Previous mistakes in industrial development have given responsible development a bad name. Will The MSB learn from past mistakes? Lakes, Wells & Rivers in this area already are dealing with the waterflow, why add contaminents to the exsting problem? Lets develop this area into something better than a polluting, eyesore, traffic jam

Dear Susan Lee,

I own property and a residence at 10190 E. Bradley Lake Avenue, Palmer, Alaska. Legal description and location of my property is 117N01E24B013 / Mile 38 Glenn Highway. I am deeply concerned about the proposed monofill dump site near my property. I believe there is great potential for contamination of the surrounding groundwater by toxic materials processed at such a site. Obviously this would have a disastrous effect on our well water, putting our health and well-being at risk. It would also release toxins into the nearby lakes and streams, which would obviously endanger the fish and wildlife in these areas.

My husband has been a builder/subcontractor for over 40 years and is quite knowledgeable about the contents of building materials such as those Central Monofill Services is proposing to recycle/dispose of at this site. He sees it is inevitable that such materials would release highly toxic contaminants through leaching into the groundwater or be dispersed into the air.

I have read the report of findings written by J.A. Munter Consulting, Inc., dated February 7, 2014 which was submitted to your department. With such research and knowledgeable conclusions presented as to the damaging effects of such a monofill site, I do not understand how the Mat-Su Borough Planning Commission can even consider issuing a Conditional Use Permit to Central Recycling Services / Central Monofill Services, allowing them to operate such a facility at this location. Please use wise caution and integrity in making a decision concerning this matter.

Thank you for your time.

Sincerely,

Patricia Kepler Goossen

The inert debris will primarily be non-hazardous shredded residual, non-recyclable waste material from construction and demolition waste. Regulation Asbestos Containing Material (RACM) and Non-RACM will also be accepted at the monofill site.*
Location: MSB Tax Parcel# N02E18C010 (2840 S. Glenn Hwy.) and 17N02E19B006 (2560 S. Glenn Hwy.); within Township 17 North, Range 2 East, Sections 18 & 19, Seward Meridian.
The Planning Commission will conduct a public hearing in the Borough Assembly Chambers, Palmer, Alaska, on this item on ***December 1, 2014***. The meeting begins at 6:00 p.m. ***Public hearings begin at 6:15 p.m.*** This may be the only presentation of this item before the Planning Commission and you are invited to attend.

This conditional use permit application will be introduced for public hearing at the **November 3, 2014** Planning Commission meeting. The Planning Commission members may submit questions to the Planning Commission Clerk concerning the matter or request for more information from the applicant at the time of the introduction. All questions and requests submitted by the Commission shall be in writing and copies will be provided to the applicant and made available to all interested parties and the public upon request. Answers to questions and additional material requests will be addressed in the staff report for the public hearing.

Commission members may not receive or engage in ex-parte contact with the applicant, other parties interested in the application, or members of the public concerning the application or issues presented in the application.

Application material may be viewed on-line at www.matsugov.us and clicking on 'Public Notices'. Application material may also be reviewed in the Borough Permit Center. If you have any questions or, would like to send us comments, concerning the proposed action, this form may be used for your convenience by filling in the information below and mailing it to the Matanuska-Susitna Borough, Development Services Division, Planning Department, 350 East Dahlia, Palmer, Alaska 99645. You may fax comments to 861-7876 or e-mail to *slee@matsugov.us*. For additional information please contact Susan Lee, Planner II, at 861-7862. Comments received by ***5 p.m., October 31, 2014*** will be included in the Planning Commission packet for the Commissioner's review and information. Please be advised that comments received from the public after that date will not be included in the staff report to the Planning Commission but will be provided as hand-outs to the Commission. If there is not enough room below, please attach this sheet to another piece of paper. **In order to be eligible to file an appeal from a decision of the Planning Commission, a ~~person must be designated an *interested party*. See MSB 15.39.010 for definition of "*Interested Party*".~~ The procedures governing appeals to the Board of Adjustment and Appeals are contained in MSB 15.39.010-250, which is available on the Borough internet home page, (http://www.matsugov.us), in the Borough Clerk's office, or at various libraries within the borough.**

Subject: Central Monofill Services Conditional Use Permit Application

Hello,

I would like to submit a comment on this permit application. I live in Palmer and it would be a travesty to allow dumping on this site. This should never be used as a dump site! I am commenting on a conditional use permit application under MSB 17.60 which has been submitted for the operation of a monofill for the disposal of inert material. The inert debris will primarily be non-hazardous shredded residual nonrecyclable waste material from construction and demolition waste. Regulated Asbestos Containing Material (RACM) and Non-RACM will be accepted at the site. The proposed site is located on MSB Tax Parcels: 17N02E18C010 (2840 S. Glenn Highway) and 17N02E19B006 (2560 S. Glenn Highway); within Township 17 North, Range 2 East, Sections 18 and 19, Seward Meridian.

Please let it be recorded that I do not want this permit to be allowed.

Sincerely,

Sandra O'Brien

7450 N Esther Dr. Palmer, AK 99645

Subject: Comment regarding CMS CUP application

Dear Planning Commission Members,

I own a home with a private well less than 1000 feet from the proposed monofill site. Central Monofill Services has included in their design a plan to run drainage ditches to the gravel pond lakes which are open to the aquifer about 500 feet from my well. Of greater concern is the massive volume of leachate that will be percolating through the 2 million cubic yards of rotting mixture of toxic material directly into my groundwater. Last year CMS officials clearly lied to commission members in its statements that the elevation of the site was greater than 10 feet above groundwater and this summer, they were busy moving dirt around to get close to 10 feet above groundwater. Now, again, they are asserting that they have the *minimum* of 10 feet when the porous nature of the gravel would not provide adequate protection even if the minimum they used was several times as much. The borough's independent hydrological evaluation of the 2014 CMS application by Munter concluded that this project can contaminate wells UP TO A MILE IN A DOWNGRADIENT DIRECTION.

Hydrogen Sulfide gas is poisonous. Most people will not live in, much less BUY a home that is polluted. Central Monofill's assertion that my property value will not be affected is clearly self-serving. The steel in the tire bales will begin breaking down within 5 years, so the dump will be completely unstable before it is even filled. The erosion from 4 wheelers on the 30-50 degree slopes will be devastating. The gravel surface of the site is too unstable to support a single house, but CMS proposes to lay 7 stories of waste on property that will subside in an earthquake, leaving their dump in continuous contact with groundwater. If a grass fire should ignite the 32 acres of tires, it could literally burn for years and this has happened in a similar dump in California. The company's assertion that the completed and closed monofill could ever end up being used as agricultural land is economically unsound and they know it.

The corporate owners continue to market their activities as "recycling". This is nonsense. The project serves no purpose other than profit the corporate owners. Central Monofill Services is a "shell" corporation with almost no assets of its own and was clearly designed by lawyers for the purpose of shielding its owners assets from any of the liability for damages the dump creates. They talk about insurance, but what insurance company in the world would insure a project that is PREDICTED to contaminate wells a mile down-gradient? Then they propose a woefully inadequate 1 million dollars (5 million dollars aggregate) to fix the damage from this environmental crime.

The proposed dump provides almost no jobs while significantly reducing badly needed revenue to the borough landfill which already has a well regulated C&D section and an asbestos cell to divert these waste streams safely.

The Glenn Highway project plans to reroute Colleen Street through the proposed monofill. Will our new safe intersection now be routed through the CMS dump, or will we continue to risk high speed collisions at mile 38 of the Glenn. Wind will take the garbage everywhere, making the scenic byway a sight after any minor wind event. I don't believe that these corporate officers who were convicted of illegally dumping garbage without a permit or even so much as a business license can ever be trusted to keep the asbestos out of the wind.

Given these conditions, any vote in favor of permitting this monofill should be unthinkable. Please protect the property rights of the residents near this site. PLEASE DO NOT PERMIT THIS OR ANY PRIVATE UNMONITORED DUMP.

Sincerely,
Stephanie Figon

Subject: Comment re: Central Monofill Services

I am writing to oppose the permit request of Central Monofill Services to operate a dump in Palmer on the Glenn Highway. My husband and two children live in Sky Ranch off of the Outer Springer. There are a multitude of reasons why this permit should, again, be denied.

1) Central Monofill Services has a proven history of dumping waste without a permit. It is deplorable that our local government would approve of this behavior by granting a permit after the fact. This sets a precedent that companies can act in violation of laws and rules and then just ask for forgiveness later. This act by Central Monofill Services is exacerbated by the fact that they took no preventive action to protect groundwater or air pollution.

2) The dump area requested by Central Monofill Services is directly accessible to our ground water (aka drinking water). If granted a permit, the message sent by the MB is that it is putting the healthy and safety of its' residents behind an economic interest. If the Borough approves this permit, with the knowledge of the risk to personal health, then the Borough is also setting itself up for lawsuits, which, in the end, will result in a greater financial loss than any revenue earned by granting the permit.

3) Regarding the revenue. It is my understanding, that the taxes paid by Central Monofill Services are not that much in excess of those paid by the property owners in Sky Ranch; and that Central Monofill Services intends to employee around three (3) people. Therefore, not only is there no great economic benefit, but there is not even a "job opportunity" benefit to the residents of the Valley.

4) The Springer system is already subject to an increase of truck and train traffic due to existing gravel pits. Has the MSB considered the increase in truck traffic in this area - an area where people still jog and ride bikes on the side of the road. In addition, what steps will the company take to reduce noise, pollution and wear and tear on our roads?

5) The area of Palmer, where the dump is proposed is subject to extremely high winds. Given the hazardous waste materials allowed to be dumped at this proposed site, this puts local residents (including farms where most of the Valley vegetable are grown) at a greater risk for air pollution. I understand that asbestos products may be dumped at this site. Asbestos is so dangerous it is no longer allowed in our schools or homes. Now imagine these chemicals blowing across the highway into residential neighborhoods and farm land.

6) I cannot comprehend why the MSB would consider taking Anchorage residents garbage. Neither Central Monofill Services, nor the Anchorage residents care about the long term affects on the residents of the Valley. Why is the Valley responsible for Anchorage trash? By agreeing to accept Anchorage waste then the MSB Assembly is giving credence to the phrase "Valley Trash."

Please consider the hazards this permit request by Central Monofill Services creates for the nearby residents of Palmer and please speak on our behalf, and not on the behalf of an Anchorage company.

Sincerely,

Rachel Gernat and Daniel Cheyette

Subject: Please support the Central Monofill Services Conditional Use Permit

Dear Susan,
I am sending this email as a concerned citizen of the community. I try to keep up with the news in our community but until recently haven't become overly involved with what I would term "local matters." This recently changed due to ongoing newspaper and television coverage on the proposed Central Recycling Services Monofill. This coverage has been so skewed against Central Recycling Services that I feel like it is time to get involved. I have read the Central Recycling Services Conditional Use Permit to the Matanuska Borough for a Central Monofill Services facility in the Valley. As a concerned member of the community, I felt it was my duty to dig just a little deeper into what seemed an unjust manhunt against a local business. I have attended community meetings concerning the proposed Monofill and have even taken the time to tour the proposed site. At no time did I, or my four children, feel unsafe on the property. We were all impressed with Central Recycling Services' concern for the environment and the community. Tonight I went online and read the Department of Environmental Conservation's report (18 AAC 60) signed by Governor Sean Parnell and Commissioner Larry Hartig. As merely a layman, so to speak, everything I have read in Article 4 of this document seems to be accurately and fairly addressed in the materials that Central Recycling Services has submitted and made accessible to the public.

It eases my mind and conscious to know that this proposal I am supporting will not only bring construction and demolition material recycling to the Mat-Su Borrough, but that it will also help bring down the cost of recycling waste across the state of Alaska. I am not sure how saving money in an conscientious and responsible way can ever be considered bad. In fact, it seems irresponsible to just take the previously processed and sorted materials and dump them back into a traditional landfill. Mixing clean waste into unknown household waste seems ridiculous. My understanding is that the proposed Monofill will only take residual material and known, non-recyclable, construction and demolition material--not household or rotten trash.

I understand why local residents may be concerned with the proposed Monofill. They are scared of the unknown. The term 'landfill' is intimidating and noxious, yet media continues to use it in regard to this proposal. I have taken advantage of the informational meetings, fact sheets and tours that Central Recycling Services has offered the community. I feel confident that Central Recycling Services and their partners will keep the promise of a safe and clean operation.

Thanks for considering my viewpoint.

Sincerely,
Ann Corbett

Subject: CMS Special Use Permit

Hello--
I am writing to express my full support for the special use permit being sought by CMS for a construction debris recycling and disposal site at mile 38.3 of the Glenn Highway. CMS will provide a needed service and at the same time will be able to reclaim what is currently an unattractive mined out gravel pit. I have discussed the potential impacts with residents of the area and have concluded their objections are based entirely on typical NIMBY attitudes. Their attempts at fearmongering went so far as for one person to tell me that the Anchorage water supply could also be in jeopardy if this business is allowed to proceed, as contaminants would travel under the Matanuska and Knik River, and leach up into Eklutna Lake, and thence into the water line to Anchorage. Hmmm.
I hope the borough will see the practicality of this proposed use of the land in question, grant the permit, and not be cowed by emotional arguments against it.

Sincerely,

Dan Lucas

Importance: Low

FOR THE PAST 8 YEARS I'VE BEEN WORKING DEMO FOR CRS AND CEI , I'VE SEEN AND HELPED THIS COMPANY START AND GROW INTO A RECYCLING LEADER IN ALASKA AND CANADA WHICH HAS SET THE HIGH STANDARDS FOR MANY TO FALLOW IN RECYCLING ! MY DEMO DEBRIS HAS BEEN PICK AND SORTED ON THE SITES TO RECOVER AS MUCH RECYCLED MATERIALS AS I CAN WITH MEN AND MACHINES THEN THE REMAINDER IS SENT TO OUR RECYCLE PLANT AND RECYCLING IS FINE TUNED AS THE MATERIALS ARE PROCESSED AGAIN AND SORTED OUT EVEN MORE COMPLETELY ! THE END PRODUCT GOING TO A FILL SITE IS A CLEAN C & D PRODUCT WITH ALL HAZARDOUS MATERIAL AND RECYCLABLE MATERIALS REMOVED ! I AM A DEMANDING PERSON ON MY JOBS TO ALWAYS GO THAT EXTRA LITTLE BIT, ANYONE CAN TEAR DOWN A BUILDING BUT TO MAKE IT LOOK LIKE A PARK WHEN YOUR DONE HAS ALWAYS BEEN MY WORD AND IS MY GOAL. THAT'S THE WAY THIS COMPANY OPERATES, THEY DON'T COVER IT UP BUT THEY CLEAN IT UP SO IT'S SAFE FOR GENERATIONS TO COME. THE DUMPS AND LANDFILLS OF THE PAST ARE WHAT I'M CONCERNED ABOUT AND YOU SHOULD BE TOO, WITH EVERYTHING PLUS THE KITCHEN SINK THROWN IN THEM ! I HAVE GOTTEN NOTHING BUT POSITIVE REVIEW LETTERS ON OUR WORK IN ALASKA AND CANADA WITH NOT ONE NEGATIVE NOTE EXCEPT FROM A FEW OTHER CONTRACTORS BECAUSE OF OUR HIGH STANDARDS THAT THEY ARE CALLED TO LIVE UP TO ! CENTRAL COMPANIES ARE ALWAYS SHARPENING THEIR TOOLS OF THE TRADE TO BE "THE LEADER" IN ALASKA RECYCLING AND CLEAN FILL SITES !
THE PEOPLE OUT THERE WITH THEIR NEGATIVE/TOXIC REMARKS AND BANDWAGONS ARE RUNNING IN FEAR OF THE UNKNOWN BECAUSE THEY HAVE NOT SPENT ONE MINUTE RESEARCHING THIS COMPANY'S TRACK RECORD OR THEIR GOALS BUT DWELL ON THE LANDFILLS OF THE PAST WHICH WERE A FREE FOR ALL DUMP SITE FOR EVERYTHING INCLUDING THE KITCHEN SINK !

THANK YOU VERY MUCH FOR TAKING THE TIME TO READ MY FEELINGS ON THIS MATTER WHICH I AM PROUD TO HAVE BEEN PART OF THIS COMPANY AND HELP BUILD IT TO WHERE IT IS TODAY !

FIRST CLASS MAIL

The Matanuska-Susitna Borough Planning Commission will consider the following:
Application or Item: *Application for a conditional use permit for the operation of a monofill for the disposal of inert material*
Matanuska-Susitna Borough Code Section: MSB.17.60 – Conditional Uses
Applicant: Central Monofill Services
Request: *An application has been submitted for the operation of a monofill for the disposal of inert material The inert debris will primarily be non-hazardous shredded residual, non-recyclable waste material from construction and demolition waste. Regulation Asbestos Containing Material (RACM) and Non-RACM will also be accepted at the monofill site.*
Location: MSB Tax Parcel# 17N02E18C010 (2840 S. Glenn Hwy.) and 17N02E19B006 (2560 S. Glenn Hwy.); within Township 17 North, Range 2 East, Sections 18 & 19, Seward Meridian.

The Planning Commission will conduct a public hearing in the Borough Assembly Chambers, Palmer, Alaska, on this item on ***December 1, 2014***. The meeting begins at 6:00 p.m. ***Public hearings begin at 6:15 p.m.*** This may be the only presentation of this item before the Planning Commission and you are invited to attend.

This conditional use permit application will be introduced for public hearing at the **November 3, 2014** Planning Commission meeting. The Planning Commission members may submit questions to the Planning Commission Clerk concerning the matter or request for more information from the applicant at the time of the introduction. All questions and requests submitted by the Commission shall be in writing and copies will be provided to the applicant and made available to all interested parties and the public upon request. Answers to questions and additional material requests will be addressed in the staff report for the public hearing.

Commission members may not receive or engage in ex-parte contact with the applicant, other parties interested in the application, or members of the public concerning the application or issues presented in the application.

Application material may be viewed on-line at www.matsugov.us and clicking on 'Public Notices'. Application material may also be reviewed in the Borough Permit Center. If you have any questions or, would like to send us comments, concerning the proposed action, this form may be used for your convenience by filling in the information below and mailing it to the Matanuska-Susitna Borough, Development Services Division, Planning Department, 350 East Dahlia, Palmer, Alaska 99645. You may fax comments to 861-7876 or e-mail to *slee@matsugov.us*. For additional information please contact Susan Lee, Planner II, at 861-7862. Comments received by ***5 p.m., October 31, 2014*** will be included in the Planning Commission packet for the Commissioner's review and information. Please be advised that comments received from the public after that date will not be included in the staff report to the Planning Commission but will be provided as hand-outs to the Commission. If there is not enough room below, please attach this sheet to another piece of paper. **In order to be eligible to file an appeal from a decision of the Planning Commission, a person must be designated an *interested party*. See MSB 15.39.010 for definition of *"Interested Party"*. The procedures governing appeals to the Board of Adjustment and Appeals are contained in MSB 15.39.010-250, which is available on the Borough internet home page, (http://www.matsugov.us), in the Borough Clerk's office, or at various libraries within the borough.**

Name: Mary Fisher for Alaskans for Litter Prevention and Recycling ***Address:*** PO Box 200393, Anchorage, AK 99520

Location/Legal Description of your property: NA

Comments: Thank you for taking comments on behalf of Alaskans for Litter Prevention and Recycling (ALPAR.) ALPAR is a 501c3 non-profit that supports economically viable recycling and litter clean up programs throughout the state for over 30 years. We serve the MATSU Borough through support for the Valley Community for Recycling Solutions (VCRS) Recycling Center at over $100,000 in services annually as well as through support for the Wasilla, Palmer, and Houston Youth Litter Patrols, MAT SU borough distribution of free ALPAR litter bags, DOT Adopt a Highway and other litter cleanup efforts.

We support Central Monofill Services' application for this much-needed monofill for specific materials that are best suited for this type of disposal. We have had an excellent relationship with CMS and their family of companies, Central Recycling Services and Central Environmental Inc. for many years. The monofill supports a recycling operation for the Railbelt and North Slope that is insuring that tens of thousands of tons of inert debris are being diverted from our state's landfills to becoming new products. The small portion of unusable materials from this manufacturing process must be disposed of economically and safely.

Since 2011, ALPAR and the residents of our communities have benefited by partnering with CRS to provide glass recycling in the Anchorage bowl, which is also utilized by many in the MATSU Borough. CRS to provide exceptional services to ALPAR and our residents to turn old glass into useful construction material with only a fraction of that material needing to be disposed after processing. Without their commitment, resources and expertise, this recycling service would not exist. They have been a positive, upstanding company to partner with, ensuring quality of product, safety of the processing operation and timely marketing of recycled glass product to users to the benefit of our communities. Based on our experience, their operation has been professional, detailed, focused on safety and environmental stewardship and responsive to community needs. We have never experienced any smells, contamination or other problems at their sites. We have seen a well run, organized and safe operation. This year, CRS donated over $9,000 in product and services towards an ALPAR-supported park improvement project again demonstrating their commitment to community. CRS received the ALPAR Outstanding Supporter Award in 2012 and the Outstanding Business Recycler in 2009. We believe that CRS/CEI and CMS will be an excellent service provider in the MATSU Borough based on our experience with them and will provide a much-needed service that the remanufacture of recycled construction, demolition and glass materials must have in order to remain viable.

Subject: Central dump

To quote Durand, "a lot of people are skewing what happened to the negative, making it seem a lot worse than it really is," regarding their short stay in the Valley last year. How can what they did be skewed negatively when it actually was negative; illegal dumping and blowing debris. And, thirty percent of the property isn't even 10 feet above the groundwater.

The issue of well water quality has to be everyone's main concern. If once contaminated, there is no going back. As pointed out there is so much unused land around, why can't they find a more appropriate dumping site? They are worried about the high dumping fees in Anchorage, we are worried about our well water and lakes, health, the look of the Valley. It would be a blight for all to see.

Please end this once and for all.

Mrs. Lee,

I support the CUP that Central Recycling has applied for. I've followed the opposition of this application and had to speak up. The proposed landfill application is for inert C&D waste only! The associated risks that people seem to think exist are completely ridiculous and unsubstantiated by scientific fact. I think the general public is highly confused and misinformed. Please use your best judgment and scientific factual evidence when making your decision.

Subject: Central Monofill Services Conditional Use Permit

I support Central Monofill Services application for a conditional use permit along the Glenn Highway.

I came to know of Central Environmental Inc. while working on a piece of public art for Alaskans for Litter Prevention. I have been to several of their sites in the Anchorage area, sourced recycled materials and have been impressed with how orderly, professional and safe their facility are.

This is an Alaskan Company that takes care of it's Alaskan employees while increasing the amounts of recycled materials that can be pulled from our local landfills without increasing costs to its residence.
CRC has also been a very generous supporters of the community donating to many local causes for many years.

Thanks you,
Rebecca Lyon

Subject: Central monofill conditional use permit

Ms lee,
I would like to comment in the central monofill services conditional use permit. I own a home in crimson view subdivision, my back yard borders the gravel pit. I grew up in Pinconning Michigan, on Bay Arenac line. All my neighbors were my family. The road I grew up on is about a mile long and there's 14 houses on it, which are all owned buy Holbrooks (my family). Growing up I could walk or ride my bike to all my cousins houses and my grandparents. The property behind all my families houses was beautiful woods with creeks and tons of wildlife. Growing up I would see deer and turkeys in the yard daily. I'd wake up to the sounds of birds, and the smell of fresh air. Getting to the point, the square mile woods behind my families houses was owned by one man. He sold the property to a company that wanted to develop the land into a landfill. My family fought and fought. In the end we lost the battle and the work began. Where we once sat and enjoyed peaceful dinners by the grill was now loud bulldozers, horns and backup alarms. Before the work began, we would see a handful of cars a day go by the house, normally it was friends or family that would wave. now it was semi after semi. Road construction started to make the road bigger so all these big vehicles would fit down the road. What was once a beautiful wooded view behind our homes was now a wide open field of dirt with a fence around it. We were horrified but had no idea what was to come. Once they started hauling garbage in the noise never stopped. However, my family did win one small battle and the equipment wasn't able to work after 10 pm so we could get a little peace and quiet. Once they started bringing garbage to the landfill, the horrible stench came with it. Some days the wind would blow towards our houses and would smell so bad you couldn't even enjoy any aspect of life. What once were beautiful homes that my family worked hard there entire lives for were now worth pennies. I could go on all day about the negative effects that dump had on our community. Please don't make me go through all this again in my lifetime. I am so scared that this might happen to me again. I moved from anchorage to Palmer a few years ago so I could live in a small, peaceful and beautiful Place. I absolutely love it there.

Central Monofill Services Conditional Use Permit

There are 2 pages, including this coversheet. Please call if all pages are not received.

Central Monofill Services Conditional Use Permit

The proposed site is located on MSB Tax Parcels: 17N02E18C010 (2840 S. Glenn Highway) and 17N02E19B006 (2560 S. Glenn Highway); within Township 17 North, Range 2 East, Sections 18 and 19, Seward Meridian.

A conditional use permit application under MSB 17.60 has been submitted for the operation of a monofill for the disposal of inert material. The inert debris will primarily be non-hazardous shredded residual non-recyclable waste material from construction and demolition waste. Regulated Asbestos Containing Material (RACM) and Non-RACM will be accepted at the site.

To Whom It May Concern:

This is a letter in regards to the disposal site that is proposed for inert material, which will contain asbestos. (there is no such thing as regulated asbestos). Being that asbestos is a dangerous material why would it be allowed off of a main road where the wind would carry the fragments of airborne material. I submit that with that kind of material it will and cannot be contained. I find that this material they want to dispose of is the cause of cancer, lung disease and death, it is one of the deadliest products ever made that has been used in homes and businesses throughout this country, they have had to remove it at a high cost financially and environmentally because of the health hazards related to it. Why would a proposal of that magnitude be even a consideration for the Mat-Su?

There have been many other solutions to the disposing of such materials throughout the lower 48's maybe this site would be a short cut for the companies wanting to dispose of it. It would cost far more for a seif-contained disposal site to be built, than to just dump it in an area that will always be contaminated. You are not going to tell the public that precautions by the employees of this project will not be protected from the debris while working with this material. So why would you place the inherent dangers for the public with this site?

Maybe if you had lost someone to asbestos your position on this matter would find you fighting to keep that which is clean and healthy for future generations recognizing that it would not stay that way once this project would be untaken.

I find it appalling that it is even being considered.

Subject: Central Recycling Services

I understand from the paper the Mat Su Bourough is against Central Recycling Services location in the valley. Let me tell you something.
We had a large driveway put in by them from recycled glass and things recycled. It saved the environment and helped us a lot. There was no mess and it helped to empty the landfill. They have had a long history of cleaning up the environment.

This company is very aware of clean living, including wells and the neighbors.
The neighbors do not want the company there for it will take away from their trespass playground. We need more companies that are concerned for our future than those just dumping trash everywhere that will not be recycled.

Please consider letting them have a permit. If you are so concerned why not have the borough clean up all the rusty old cars and trash along the roads cleaned up.

You will not find a more concerned company and reliable employees than Central Recycling Service. They may have a brief history in the valley but a very good one world wide.

Thanks for your consideration. Ina and Richard Ayers

October 29, 2014

Dear Planning Commission members:

I am submitting comments on the proposed landfill near the Glenn Highway in the Palmer – State fairground and residential areas.

This landfill has been stopped by the borough before. It should now be completely shut down and the area should be restored to pre gravel extraction conditions.

There are many reasons for this restoration however; the health of families in many neighboring subdivisions is paramount. My primary concern is that of water table contamination. I know from first-hand experience the conditions of drinking water are drastically affected from disturbance at the gravel pit-dump site. My daughter and her children live in one of the nearby subdivisions. Unpermitted dumping at the site in the past has caused sediment and a foul taste in the water of my daughter's family well.

The Borough Planning Commission Finding of Facts and Conclusions of Law in the denial of a permit show many reasons why the dump site should not be allowed. The applicants complete disregard to windblown trash as well as their dumping of trash without an MSB or ADEC permit into a gravel pit which most likely exposes the nearby water table to contaminates is a primary reason this project should be permanently enjoined from going forward.

Item 35 of the Planning Commission Findings: "According to documentations and studies the proposed monofill site is located where the topography, geology, hydrology and soil are inadequate for protection of ground and surface water quality." This alone should be enough to warrant a finding against the permit. There is no way to seal the ground from the spreading of toxics materials into the surrounding aquifer if they are placed into the proposed monofill site. This aquifer supplies the surrounding thousands of families with drinking, bathing, cooking and laundry water.

Thank you for your time and consideration.

Subject: Central Monofill Services Conditional Use Permit

I am voicing my support for the Central Monofill Services Conditional Use Permit. There are a host of reasons that make environmental and economic sense to support this effort. There is a lot of misinformation, distortions, flat out lies, and general fear mongering by a few folks that are against the program. They are either very confused or have some self serving agenda for opposing this effort. I sincerely hope all the facts will be objectively considered and the permit issued.

Thanks,
Doug VanWingerden

Subject: Monofil Dump

October 29, 2014

TO: Mat-Su Borough Assembly

I am a resident of the Sky Ranch neighborhood which is adjacent to an existing gravel pit and with close proximity to a proposed monofil dump.

This large gravel pit/asphalt plant already exposes us to noise pollution and inconvenient railway disruption. In addition, prevailing winds carry airborne pollution, odors, and smoke from a dump site at the intersection of Inner Springer and Rebarchek Road. Assurances that this is not harmful are found hard to believe. The potential for additional pollution to the air and private wells from the proposed project site abound and should not be ignored.

Assurances aside, this company has already demonstrated mistrustful behavior by dumping material without the required permit. Both the Borough and DEC cannot guarantee that proper enforcement of the permit restrictions will be conducted.

Please do not allow this company to turn Borough land into a dumping station for the building refuse of Anchorage.

My family is asking you, the Assembly member, not to award CMS a permit that endangers our community.

Respectfully,

Gary and Eileen Gearhart

Subject: Central Monofill Services Conditional Use Permit Comment

My name is Kellie Ballard'Chambers and I reside on Bradley Lake ave, which is approximately one block from the southern border of the proposed mono fill site. I have several concerns, both short and long term, regarding the dump site and the possible effects it could have on surrounding property values as well as physical health hazards to those that may be affected. This site has a history of extremely high winds (I realize CMS's legal council has wind reports from the airport which is 5 miles away and not an accurate gauge to wind speeds at the site) and an open aquifer that feeds into the surrounding wells and other bodies of water.

State Law requires that disclosure to the buyer of real property be made if a dump site or gravel pit is within a one mile radius of said property. It stands to reason, because of mandatory state law, that theses types of projects negatively affect property resale values, more so if those projects contain hazardous materials such as asbestos vrs the existing abandoned gravel pit.

According to Central Monofill Service's own Borough application, the inert debris will "primarily" be non hazardous, shredded, residual, non recyclable waste material from construction and demolition waste. According to Websters dictionary, it defines "primarily" as meaning "for the most part". CMS defines hazardous material "as a material containing any percentage of asbestos". According to OSHA, there are over 400 materials that are deemed toxic or hazardous and require regulation. According to EPA's Toxic Substance Control Act, there are more than 62,000 chemicals or substances in their inventory list, some of which can be found in CMS's own defined inert material. This is insanity to even consider disposal any where near the open aquifer which feeds the surrounding homeowner wells and state lakes.

According to the Matanuska Susitna Borough code officer, Mark Whisenhunt, in his report dated 4-29-2013, in his contact with Stuart Jacques,CMS President, noted that they hauled "daily cover" aka "screened fines or topper" material to the proposed site prior to obtaining a permit. This material consisted of Styrofoam, carpet and various types of plastics along with material that according to the Mat Su Borough application is not permitted at the mono fill, under "household waste". CMS and Shane Durand were issued six citations and were ordered to remove the screened fines, some of which was buried in ground water. This trash water was then being pimped into the dredge pond that feeds directly into the aquifer that supplies all the surrounding lakes as well as private wells.

I do not have much confidence in a company who makes up their own definitions for what is and isn't hazardous, and who has already violated their very own guidelines and procedures for responsible disposal of inert materials by their own definition.

According to CMS's own application, "the facility at CRS abides by all regulations and permit conditions regarding inert debris handling, placement and sorting of material, therefore no violations of waste disposal or improper processing will take place at the monofill". Violations have already occurred prior to CMS having an approved permit in hand. This leaves no confidence in this company to properly monitor themselves with the potential giant risks involved with contamination.

Subject: CMS Response
Attachments: CMS Response.PDF

Susan,

Attached is my response regarding the Central Monofill permit.

To whom it may concern,

My name is Grant Goulet and I have been working for Central Recycling Service (CRS) for over four years. I have had the opportunity to contribute to many projects around CRS in those four years whether it be expanding the final product bin for aggregate material, installing and designing a water misting system for the facility to keep dust down during the summer months, or running the tip floor and inspecting loads as they come in to prevent hazardous waste from entering the final shredded residual. I have done it all, and have expanded my knowledge of Construction and Demolition (C&D) recycling that I would not have had the opportunity to learn without this job. I am a prime example of CRS providing jobs and training to its employees. Approval of the CUP will bring more jobs to the valley

Now I work in the office and assist the Operations Manager with the daily operation of the facility. In this position I realize that it would be unrealistic for CRS to operate without having a monofill to dispose of inert shredded residual. It is also not responsible to take the residual material we create that is free of hazardous and putrescent materials and mix back into household landfills that are full of contaminants. A day may come where landfill waste is mined to recover resources and a monofill could be a preferred resource since it will be a consistent product from a known place without household waste mixed in it. Monofill Services to operate and dispose of inert material in a safe and effective way.

Sincerely,

Grant Goulet

Subject: Comment Against the CEI permit

Ms. Lee, please confirm receipt of this email via return email. Thank you in advance.

CEI has proven to be a bad neighbor on several occasions, not the least of which was the bad faith shown in dumping waste before it was authorized. What is there to prevent them from getting the permit and then allowing trash and debris to fly all around Palmer once they have their permit? Is there a measure in place that would require them to take care of the trash?

What's to prevent them from contaminating the groundwater - sure they "say" they won't but why can they be believed? The Koch brothers surely stated that they wouldn't contaminate the groundwater in Fairbanks... There are 50 wells that have the potential to be contaminated. Will the Borough require CEI to take out insurance against future contamination in perpetuity? Is the Borough willing to pay for additional testing on a yearly basis to ensure that the groundwater isn't being contaminated? Is the Borough willing to take responsibility for developing new water sources for people potentially being affected by a potential bad actor once CEI has contaminated the water, declares bankruptcy and leaves? What happens if, like the Koch Brothers, they leave and leave us with contaminated water? Who will foot the bill for that? Who will pay for lost property values because we don't have potable water?

Subject: Dump site permit

We recently moved to Sky Ranchsudivision in the Matsu Valley. The prime reasons we chose this community were the consistent property values due to a strong homeowners association and the pride of ownership shown by the property owners. A building material dumpsite so close to our homes will not only devalue the area, but potentially put the residents in danger from toxic runoff into our water systems, wells and lakes. Air quality could be compromised from asbestos or other airborne contaminants. Our children deserve better.

We strongly request that the dump permit be denied.

My name is Deborah Patrick. I live in Palmer at 4775 S Crabapple Ct. I am unable to attend the public hearing regarding permit application under MSB 17.60 on December 1st. I would like to make my displeasure known regarding this application. I do not think this is a project that should be near any place that is populated considering the nature of waste to be deposited at this site. Specifically, any type of asbestos, inert or other. Regulated or not, there will be the possibility of these containers failing in the future. Such materials should not be disposed of anywhere near public use areas, or residential areas. I am urging the Mat-Su Borough to deny this application in favor of a better thought out location.

Subject: Central Monofill Services Conditional Use Permit Application Public Comment

Ms. Lee,

I would like to comment on the Central Monofill Services Conditional Use Permit Application. Last year my boyfriend purchased a home on Vermillon street. It backs up to the gravel pit. Prior to moving to Palmer, he lived in Anchorage for 7 years and I lived there for 5. We hated the hustle and bustle of Anchorage, the lack of privacy and the traffic. We immediately fell in love with Palmer and our home. Every night we spend time in his beautiful back yard shooting our bows, playing with our dog and enjoying Pioneer Peak.

I'm afraid that our beautiful life will be ruined if the Central Monofill Services is allowed to build a landfill. I'm terrified our water will be polluted and we will find trash in our yard. Our neighborhood is one of the windiest in the Valley and I'm scared litter will end up in our backyard and harm my dog. Also, I routinely fish nearby at Echo Lake and enjoy being able to drive less than a mile down the road and spend a peaceful evening catching trout. It's really a hidden gem. If there is any risk of our drinking water or the fish being polluted, it's not worth it.

We chose to purchase where we did because we love the neighborhood and it's the perfect place for commuters. We're afraid that if a landfill is built our housing price will plummet and we will never be able to resell our home, which will ruin our future. In addition, the MatSu Convention and Visitors Borough is about to begin construction on the new Scenic Byway & Gateway to Palmer. This will bring increased tourism numbers to the Valley, which is good for our community. I fear if there is a landfill nearby the value and the appeal will drop drastically.

Please help us save the community we love for generations to come.

Palmer, AK 99645

Re: Central Monofill Services Facility

Dear Commissioners,

On behalf of Alaska Waste, I support the planning and development of an inert waste monofill site. As a waste management company in the Alaskan waste industry, I can see a construction and demolition monofill site as solely a benefit to the local community.

Central Recycling Services (CRS) is the only full-scale Construction & Demolition Recycling Facility in Alaska. They are known for their ability to divert construction and demolition materials from the Alaskan landfills, to meet recycling quality standards per the construction requirements of Leadership of Environmental and Energy Design (LEED), and to meet all regulations required when managing and disposing of hazardous materials.

Prior to CRS' existence, there was not an option to recycle reusable materials from the construction and demolition industry. Over the past four years, CRS helped the local construction and demolition contractors and box store companies, to extend the life of the landfill by diverting over 77% of all of the construction materials brought to their recycling facility in Anchorage.

With an increasing demand for recycling within Alaska, a need for inert debris monofills are more essential. A responsible environmental company, such as Central Recycling Services, has the ability to benefit the entire Borough by recycling as much of the construction and demolition materials and therefore building an inert debris monofill.

Sincerely,

Matt O'Connell
Division Vice President

Subject: Central Monofil Conditional Use permit application

To the planning and zoning commission --
Ladies and Gentlemen

I write in support of the application of Central Monofil for a Conditional Use permit to establish a monofil site for recycling inert construction debris.

I have lived in Anchorage since 1982). There is a significant need for greater recycling capacity for construction debris in the region. South-central Ak is in re-development and a substantial amount of re-useable material is being generated.

The applicant is one of the Central Environmental, Inc. companies. I have known the company and its owners professionally for many years. They are, in my opinion, the "gold standard" in Alaska for integrity and environmental responsibility in a highly regulated industry.

Thank you. Mike Kreger 5363 Sillary Circle Anchorage, Ak 99508 (907) 230-1451

FIRST CLASS MAIL

The Matanuska-Susitna Borough Planning Commission will consider the following:

Application or Item: *Application for a conditional use permit for the operation of a monofill for the disposal of inert material*

Matanuska-Susitna Borough Code Section: MSB 17.60 – Conditional Uses

Applicant: Central Monofill Services 99645*9307 H007

Request: *An application has been submitted for the operation of a monofill for the disposal of inert material. The inert debris will primarily be non-hazardous shredded residual, non-recyclable waste material from construction and demolition waste. Regulation Asbestos Containing Material (RACM) and Non-RACM will also be accepted at the monofill site.*

Location: MSB Tax Parcel# 17N02E18C010 (2840 S. Glenn Hwy.) and 17N02E19B006 (2560 S. Glenn Hwy.); within Township 17 North, Range 2 East, Sections 18 & 19, Seward Meridian.

The Planning Commission will conduct a public hearing in the Borough Assembly Chambers, Palmer, Alaska, on this item on ***December 1, 2014***. The meeting begins at 6:00 p.m. ***Public hearings begin at 6:15 p.m.*** This may be the only presentation of this item before the Planning Commission and you are invited to attend.

This conditional use permit application will be introduced for public hearing at the **November 3, 2014** Planning Commission meeting. The Planning Commission members may submit questions to the Planning Commission Clerk concerning the matter or request for more information from the applicant at the time of the introduction. All questions and requests submitted by the Commission shall be in writing and copies will be provided to the applicant and made available to all interested parties and the public upon request. Answers to questions and additional material requests will be addressed in the staff report for the public hearing.

Commission members may not receive or engage in ex-parte contact with the applicant, other parties interested in the application, or members of the public concerning the application or issues presented in the application.

Application material may be viewed on-line at www.matsugov.us and clicking on 'Public Notices'. Application material may also be reviewed in the Borough Permit Center. If you have any questions or, would like to send us comments, concerning the proposed action, this form may be used for your convenience by filling in the information below and mailing it to the Matanuska-Susitna Borough, Development Services Division, Planning Department, 350 East Dahlia, Palmer, Alaska 99645. You may fax comments to 861-7876 or e-mail to *slee@matsugov.us*. For additional information please contact Susan Lee, Planner II, at 861-7862. Comments received by ***5 p.m., October 31, 2014*** will be included in the Planning Commission packet for the Commissioner's review and information. Please be advised that comments received from the public after that date will not be included in the staff report to the Planning Commission but will be provided as hand-outs to the Commission. If there is not enough room below, please attach this sheet to another piece of paper. **In order to be eligible to file an appeal from a decision of the Planning Commission, a person must be designated an *interested party*. See MSB 15.39.010 for definition of "*Interested Party*". The procedures governing appeals to the Board of Adjustment and Appeals are contained in MSB 15.39.010-250, which is available on the Borough internet home page, (http://www.matsugov.us), in the Borough Clerk's office, or at various libraries within the borough.**

Comments:

See attached comments

Note: Vicinity Map Located on Reverse Side

A large private dump (aka monofill) is being proposed to be located along the Glenn Highway just north of the Matanuska Lakes State Recreation Area, which is composed of eight lakes in the Bradley/Kepler lake complex and is the Gateway to Palmer.

A private Anchorage-based company, Central Monofill Services has yet again submitted an "Application for a conditional use permit for the operation of a monofill for the disposal of inert material", defined loosely as construction/demolition waste, from Anchorage. Similar to the company's unsuccessful attempts to locate in the Chugiak area the company is repeating its' efforts to gain approval here.

Perhaps before a decision is rendered, a few points for discussion might be considered by our MatSu Borough government with its variety of elected and appointed representatives. Please, let us all consider the following five discussion points:

1. Perhaps all waste should be processed and deposited within the Borough in which it originated.
2. Public use disposal sites with fair and clear regulations and daily oversight and management already exist for this proposed purpose. These sites are currently utilized by hundreds of contractors and private citizens in both the MatSu and Anchorage Boroughs, year round under well-established public health and safety guidelines. There should be no need for a private monofill exception.
3. The significant number of families who live in the Crimsonview, Heavenly Meadows and Pioneer Meadows subdivisions and those living adjacent to Irene Lake, Canoe Lake and Bradley Lake surround the proposed monofill site. All of these families, mothers, dads and children, are entitled to clean air, clean water and clean lands, all of which may be seriously threatened by a monofill operation amongst these family homes. Why should our governmental representatives subject the MatSu Borough to future lawsuits for violation of these rights to public health and safety?
4. The proposed land use area surely has higher value to the Borough and its' people, and including possibly the City of Palmer, as the potential site for housing, a public park or recreational fields, schools or multiple small businesses, most of which would add positively to the tax base of our communities.
5. In both the private sector and in government it is a serious burden to explain why someone who has been recently untrustworthy should continue to receive continued public support. We need to hire trustworthy individuals, companies and governmental representatives who place the public good and the health and safety of our moms, dads and children above corporate convenience. It is our impression that the good people of this Borough appreciate good government and will support common efforts for the greater enhancement of the overall community.

Subject: Re: CRS Conditional Use Permit for the Monofill in Mat Su Borough

My Name is Anette Lewis.

I have held a residence in the Mat Su Borough for over 10 years now. I grew up in the Matanuska Valley. It is my home and I would never support something that I thought would diminish it.

I have worked in the construction field since 2002 and have seen just about every aspect of a construction project. I don't know anyone who doesn't appreciate a new home or office which require construction. Every construction project produces debris, and the end result of this mass quantity of debris should NOT be the landfill. Supporting a company that will remove as much of that debris for recycling and reduce the amount that goes into any type of fill just makes sense. I know that the fill going into the Proposed Monofill would be non-toxic, meaning it would not pollute the ground nor the water; after all, it is all the same materials as the buildings and homes we all dwell in.

I would like to see a responsible company come in and safely handle these materials at a site that is secluded from the view of most and at which hauling materials would be from a main highway keeping the trucking out of residential areas.

I only see this Monofill as a positive venture for our growing community.

Subject: Monofil

I support the monofil in Palmer. This is private property that the owner should be allowed to develop. After checking on the company, visiting their monofil in Fairbanks, touring their facilities in Anchorage I feel this is a responsible company. They will be providing jobs which the valley needs. Also 50-70 % of the product they recycle from demo is sold in the valley. We shouldn't stop responsible development.

When people complain about trash blowing around that can be seen just about anywhere in the Valley. Also people complaining need to remember this is private property not their personal recreational area.

I have lived in Alaska since 1964 and husbands family came to the valley in the late 1930's

Comment on an application for a conditional use permit for the operation of a monofill for the disposal of inert material at 2840 and 2560 S Glenn Highway

I am Roseann Leiner, and I own a residential property at 2340 S Killarney Drive, which has access to Canoe Lake.

My comments are as follows: As as a user of Canoe Lake and an owner of a well for residential use at 2340 S Killarney Dr., I strongly urge that the application for the monofill disposal be rejected.

If monofill disposal is on a porous gravel surface overlying a high water table, the risk of contaminating the local aquifer is great. The monofill may have some compounds that react with water and leach into the ground water. Standing water has been visible on the subject parcels in recent years, and may be tied to water levels at Canoe Lake, Irene Lake, and Bradley Lake. The surface water indicates a high water table on the subject parcels for which the permit is requested. Residential wells and lake ecosystems are valuable and can be ruined by contamination.

Please do not risk contamination of the local water aquifer by monofill disposal.

Thank you,
-Roseann Leiner

Subject: Proposed CMS DUMP Palmer AK

To: Planning Commission;

We Miguel and Annette Toro are residents in the Majestic Hills Subdivision off of Inner Springer. We would like to plead with you not to approve and give the permit for a Dump that had been "tentatively approved" by Alaska DEC.
This can have enormous risks to our environment and inevitably to our Health. Having such a dump that could contaminate our water (wells, lakes and streams)(ex:may contain creosote, lead,acrylic, chromium, pentachlorophenol, phenol-formaldehyde resins and other contaminants to our ground water), air quality from wind caught debris and contaminated material (ex: Asbestos, Black Mold) Please remember our wonderful "Palmer Winds" that could easily spread any debri to our beautiful and clean Matsu Borough here in Palmer.
As we have learned with other dump sites in many Cities and States it has proved that although it starts out to be "controlled" dumping. It has been found to house poisonous debris and toxic waste causing cancer in people living near and using the well and ground water, not to ignore the two headed cows.
Thank you for taking into consideration our protest for it is to benefit all of the People of Palmer. We don't want to be know as "Palmer the Toxic Waste Dump".

Sincerely,
Miguel and Annette Toro

Please read attached letter. Thank you,

Brian Groseclose

October 28, 2014

To: Mat-Su Borough Assembly

I am requesting that the Matsu Borough Assembly members DO NOT award a permit to CMS for the monofill dump site. I live in the Sky Ranch subdivision and we already have enough noise and air pollution issues here. The sewer smell is disgusting from the settling ponds less than one mile from here. There is a gun range near Mt View Estates that law enforcement uses for target practice for hours on end. We have the dump near the fair grounds that occasionally brings foul odors our way. We DO NOT need more pollution with a dump across the highway that will almost certainly contaminate our drinking water! There are already toxic wastes that have been dumped in this area and if a permit is issued the problem will escalate into serious health issues for all of the local residences as well as wildlife. Our property values will decline and we will not be able to sell our homes if any groundwater becomes contaminated. There are millions of acres of land all over Alaska and this company wants to take the easy and convenient way to make money while not giving any concern to the citizens in Palmer or the local area. Please DO NOT issue this permit. If you choose to issue it, I hope you fully accept the responsibility for the outcome when things go bad in the community. I chose to live in Palmer for the wonderful community it has always been. Please don't destroy it just for money or the convenience of a close dumping ground. Think of the long-term effects on our future generations of family members that depend on a clean and healthy environment to live in. Thank you,

Brian Groseclose

Subject: Comment on the CMS dump

October 28, 2014

To: Mat-Su Borough Assembly

I am making this comment on behalf of the 50 lot- owners in Sky Ranch subdivision, a nice quiet community on the east side of the Glenn Highway, adjacent to the gravel pit and barely a "stone's throw" from the site of the private monofil dump.

All of us in Sky Ranch are outraged that the DEC has approved the project and we strenuously implore our borough assembly now to deny this private company a permit to proceed.

We already suffer airborne pollution, odors and smoke from a dump site at the intersection of the Inner Springer & Rebarchek road near the fairgrounds. We value the sweet and clean water from our private wells that are now endangered by this project. Why must we suffer our residential community to become the dumping site for Anchorage via this private company? They have already demonstrated they cannot be trusted as they began dumping material in advance of a permit. Neither do we trust the DEC to conduct oversight of their dumping activity. While area residents choked with eyes burning recently due to thick smoke from mysterious fires that burned and smoldered near Rebarchek Rd, we were told it was all good and safe, nothing to worry about.

Such assurances ring very hollow and we feel powerless in this fight against a private company seeking to turn our clean and healthy community into a private dump for all the building projects in southcentral Alaska.

Please assembly members, we respectfully entreat you NOT to award CMS a permit to destroy our community.

Barbara Landi

President, Sky Ranch at Pioneer Peak HOA

Subject: Proposed Monofill Landfill near Kepler & Echo Lake

Re: Proposed CRS Mono fill Dump / Palmer, Alaska

Dear Mat-Su Assembly Members,

I am writing this letter as a private citizen and resident of Alaska for over 38 years. I have concerns about a proposed mono fill near Kepler and Echo Lake. I believe heavy industrial uses like mono fill dumps DO NOT belong next to established family neighborhoods, parks and lakes and drinking water. Science has proven these landfills are toxic to our water and our air. Unfortunately the laws have not caught up with the findings. You can visit this web page link below for more information about toxic mono fills

http://www.neha.org/pdf/JEH/columns/JEH_0908_ATSDR.pdf

Background:

Central Recycling Services is proposing to use a parcel of land in Palmer to allow heavy industrial uses, including the immediate operation of a private, unlined construction and demolition debris dump (a 'mono fill'). Central Recycling Services Inc. would create and operate the dump for the exclusive disposal of their refuse obtained primarily from demolition projects on JBER. The parcel is proposed directly north of a popular tourist attraction, Kepler and Echo Lakes and hundreds of nearby homes. Access into the dump will be via Glenn highway, with truck traffic increasing to dozens a day in and out of the location. Central Recycling has chosen to ignore the voices of its neighbors and go forward with the application to the Palmer Assembly in hope of their approval.

What the C & D Landfill will potentially do:

·allow Central Recycling, Inc. to profit at the borough tax payer's expense by forfeiting dump fees at the Palmer Landfill which already operates a facility that can specifically handle this kind of waste;

· heavily increase truck traffic and result in potential conflicts along the Glenn Highway

· potentially cause major environmental catastrophes, including surface and subsurface water contamination from an unlined landfill into thousands of wells and lakes in the area.

· spew high concentrations of hydrogen sulfide gas into the surrounding air; hydrogen sulfide is a poisonous, flammable, and colorless gas with a characteristic odor of rotten eggs, produced when gypsum board (Sheetrock, Drywall) becomes wet - common complaints from these types of mono fills across the country, including an existing, and active mono fill adjacent to the Birchwood Airport, in Chugiak, Alaska, include permanent or long-term effects such as

nausea, headache, eye irritation, difficulty in breathing, poor motor function, and loss of attention and memory; there have been documented complaints at Birchwood Airports mono fill of hydrogen sulfide gas.

Pleas view CBS Ch11 report - Birchwood mono fill complaints

https://www.facebook.com/video.php?v=371943332942484&set=vb.273836102753208&type=3&theater

· threaten the HEALTH of established adjacent neighborhoods, Tourist using nearby campgrounds and parks and LOCAL Recreational USERS as well as bring about the decrease of surrounding property values.

I urge you to oppose this mono fill. It is NOT safe. Central recycling has other options. They can and should use the local borough landfill.

Sincerely,

Theresa Daily

Construction and Demolition (C&D) Landfills: Emerging Public and Occupational Health Issues

Editor's note As part of our continuing effort to highlight innovative approaches to improving the health and environment of communities, the Journal is featuring a bimonthly column from the U S Agency for Toxic Substances and Disease Registry (ATSDR) The ATSDR, based in Atlanta, Georgia, is a federal public health agency of the U S Department of Health and Human Services ATSDR serves the public by using the best science, taking responsive public health actions, and providing trusted health information to prevent harmful exposures and diseases related to toxic substances

The purpose of this column is to inform readers of ATSDR's activities and initiatives to better understand the relationship between exposure to hazardous substances in the environment and its impact on human health and how to protect public health We believe that the column will provide a valuable resource to our readership by helping to make known the considerable resources and expertise that ATSDR has available to assist communities, states, and others to assure good environmental health practice for all served

The authors of this month's installment, Michelle Colledge and Lynn Wilder are with ATSDR's Division of Regional Operations and Division of Health Studies, respectively Dr Colledge is a senior research officer, and earned her MPH from Florida A&M University and her Ph D from the University of Illinois at Chicago School of Public Health She is a lieutenant commander in the United States Public Health Service, and has worked for ATSDR since 1999 Since working in the region 5 office, Michelle has lead multi-agency and multi-disciplinary teams in public health investigations, risk and exposure assessment, and provides technical assistance to partner agencies for emergency response activities Lynn Wilder is a senior environmental scientist and received her M S in industrial hygiene from the University of Pittsburgh She is a certified Industrial Hygienist and is a Ph D candidate at the University of Washington's Department of Environmental and Occupational Health Since joining ATSDR in 1989, she has worked in areas of emergency response, health and exposure investigations, and health studies

Historically, construction and demolition (C&D) debris landfills have been considered nonhazardous operations, containing relatively inert wastes such as concrete, asphalt, wood, metals, gypsum drywall, and roofing materials. In recent years, however, it has become increasingly clear that emissions resulting from the decomposition of gypsum drywall and organic debris are a public health issue. Drywall, comprised of gypsum ($CaSO_4 \cdot 2H_2O$), breaks down into hydrogen sulfide and other sulfur compounds under anaerobic conditions and in the presence of water. When exposed to water, the sulfate in the gypsum is dissolved in landfill leachate (Townsend, 1998). Under the same environmental conditions, organic debris degradation produces other flammable gases such as methane. As a result, surface and subsurface fires may occur at C&D landfills (Federal Emergency Management Agency [FEMA], 2002).

Drywall can be a significant constituent of C&D wastes. Depending on the type of construction, it comprises between 5% and 25% of total C&D volume generated (Townsend et al., 2000; United States Environmental Protection Agency [U.S. EPA], 1998). In the United States, C&D waste comprises a considerable portion of the overall solid waste stream. The U.S. Environmental Protection Agency (U.S. EPA) estimated that over 136 million metric tons of building-related wastes were generated in 1996 (U.S. EPA, 1998). Approximately 35%–40% of these wastes were landfilled in C&D facilities. As a comparison, this amount of C&D waste was only slightly less than the 190 million metric tons of total municipal solid waste (MSW) generated that same year (Clark, Jambeck, & Townsend, 2006). In 1996, approximately 1,900 C&D landfills were operating in the United States (U.S. EPA, 1998). At these sites, gas emissions to ambient air are influenced by a number of factors, including, but not limited to, the volume and composition of the waste (particularly gypsum drywall content); engineering design and controls; the condition, composition, and thickness

of the landfill cap; and leachate collection, removal, and handling practices.

Because U.S. EPA does not specifically regulate the operations of C&D landfills, C&D regulation is the responsibility of individual states. Clark and co-authors (2006) recently reviewed and summarized state C&D landfill regulations across the country. The authors found little consistency from state to state in the siting and engineering design requirements of these facilities, in regulatory oversight and rules, or even in a state's definition of what constitutes C&D waste. The authors did find, however, that state standards are generally far less stringent for C&D facilities than for MSW facilities (Clark, Jambeck, & Townsend, 2006).

The Agency for Toxic Substances and Disease Registry (ATSDR) and its federal, state, and local health and environmental agency partners have recently investigated a number of C&D landfills with gas emissions that caused significant community health concerns. Community exposures vary, but are generally greatest during stable meteorological conditions and are generally diurnal with the highest concentrations in ambient air in late evening and early morning hours. At some of these sites, concentrations of hydrogen sulfide gas in residential ambient air were at or above levels known to cause adverse human health effects. At an Ohio C&D landfill, hydrogen sulfide concentrations in residential ambient air approached the National Institute of Occupational Safety and Health (NIOSH) recommended exposure limit (REL) for the occupational ceiling value of 10 parts per million (ppm) (ATSDR, 2003). Improper leachate management at the same site also resulted in community hydrogen sulfide concentrations of up to 95 ppm on at least one occasion (ATSDR, 2006). This concentration is just below the NIOSH immediately dangerous to life and health (IDLH) level of 100 ppm over 15 minutes.

Under normal conditions, hydrogen sulfide is a colorless, flammable gas. It has an odor threshold as low as 0.5 parts per billion (ppb) (ATSDR, 2006), and is typically characterized as smelling like rotten eggs or sewage. When inhaled, hydrogen sulfide readily enters the blood stream via diffusion through pulmonary alveoli. The majority of hydrogen sulfide is metabolized through oxidation into thiosulfate, then further oxidized to sulfate, which is rapidly excreted in the urine. People with preexisting respiratory conditions or immature respiratory systems are more likely to experience adverse health effects from hydrogen sulfide exposure. Those with cardiac or nervous system disorders may also be more likely to experience adverse outcomes from hydrogen sulfide exposure. Although the exacerbation of preexisting respiratory conditions (e.g., asthma) and neurological effects (e.g., headache, nausea, and fatigue) have been noted at low levels (between 10 and 100 ppb), to date, quantifiable irritant effects levels have only been reported with exposures in the low ppm range (Bhambini, Burnham, Snydmillar, MacLean, & Lovlin, 1996a, 1996b; Campagna et al., 2004; Jappinen, Vilkka, Marttila, & Haahtela, 1990; Kilburn & Warshaw, 1995; Kilburn, 1997; Kilburn, 1999). With acute exposures at concentrations at or above 100 ppm, serious injury and death are possible (Hirsch & Zavala, 1999; Milby & Baselt, 1999; Parra, Monso, Gallego, & Morera, 1991; Reiffenstein, Hulbert, & Roth, 1992; Snyder, Safir, Summerville, & Middleburg, 1995; Tvedt, Edland, Skyberg, & Forberg, 1991; U.S. EPA, 2003).

Although ATSDR is not an occupational health agency, staff members have noted worker health and safety issues at numerous C&D landfills. Generally, these facilities have no employee training programs on the use of personal protective equipment and no on-site monitoring programs for common C&D gases. In one case, several employees either lost consciousness or became nauseated and evacuated the work area (Florida Department of Health [FDOH], 2007). In November 2007, four employees died as a result of exposure to high concentrations of hydrogen sulfide while attempting to repair a leachate pump at a C&D landfill in Superior, Wisconsin (Einhorn, 2007). Surface and subsurface fires at C&D landfills also pose a physical hazard to site employees.

The removal of drywall from the waste stream would reduce the potential of hydrogen sulfide generation from C&D facilities. Drywall recycling is an emerging market, and has the potential to significantly diminish the quantity of drywall going into C&D landfill facilities and reduce the potential of human health effects from exposure. Most drywall waste is generated from new construction (64%), followed by demolition (14%) (California Integrated Waste Management Board [CIWMB], 2008). Scrap from new construction is the primary focus of today's drywall recycling market, but future recycling strategies may also include recycling demolition drywall wastes (Townsend, 2003).

Weak regulations that govern C&D facilities at the state and local levels make addressing exposures at these sites an onerous and complicated process. Also, in the absence of a federal ambient air quality standard for hydrogen sulfide, many states have promulgated their own hydrogen sulfide standards—but others have not. Without these kinds of standards, requiring changes in facility operations that lead to reductions in community exposures is difficult at best.

The issues of national consistency and the potential for adverse effects on human health necessitate a dialogue about how best to manage C&D debris while minimizing its effects on neighboring communities. When health issues arise, it is challenging for some states to protect human health from the consequences of inadequate C&D management. Negative public health impacts would be avoided if more careful consideration was given to C&D landfill siting, design, management, and closure. Such an approach would protect health and quality of life for neighboring residents and employees.

To: Susan Lee
Subject: Proposed Monofill

To the Mat-Su borough planning commission and Mat-Su Borough Staff:

I am a proud supporter of the CMS Proposed Monofill on the Glenn Highway. I was born and raised in the Matanuska Valley and am a lifelong Valley resident, my family has been in the Matanuska Valley since the late 1930's. I work for Central Recycling Services and I support the proposed monofill because of facts not feelings. It makes me sick to see the lies that have been said about CMS and Shane Durand. The main people in opposition of the proposed monofill have spread propaganda, mislead, and blatantly lied to the general public regarding this proposed monofill. The very premise of their opposition is a lie, "Palmer Toxic Dumping". If I was a member of the general public with no knowledge of the proposed monofill and I read this, I would be in immediate opposition. They use powerful words to incite an emotional response in people who would otherwise take no interest in the proposed monofill, which would be fine if it wasn't based on a lie. However, the truth is, this material comes from buildings and homes that are occupied by humans. The material that would be placed in the proposed monofill has undergone more screening, testing, and sorting than the material that goes into any other monofill in the State of Alaska. Any hazardous materials, including asbestos, have been removed from the waste stream and dealt with properly (this is not speculation but a fact because I have personally seen it done). This is not to say that any other monofill is doing anything wrong but to say that we are a recycling company first and foremost, we process all of the material that comes through our facility. CMS is not inventing new materials to put into a monofill, these are the same materials that go into the Mat-Su Borough's monofill and Alaska Demolition's monofill, with one differentiating fact, the material that would go into the proposed CMS monofill has been processed and sorted to ensure that all hazardous materials are properly dealt with!!!!!

Every load of material that is delivered to our recycling facility is delivered under the knowledge that we do not accept hazardous materials, this is clearly outlined in our credit application and on our website. When the load is dumped at our facility, it undergoes visual inspection by trained personnel with the following tier of importance: 1.) Does the load contain anything hazardous? 2.) What is recyclable? If the answer to the first question is not a definitive no, we put the load aside for further testing to ensure that it does not contain hazardous materials. If the load does contain hazardous material, it is cleaned up in accordance with all applicable rules and regulations. If we are sure the load contains nothing hazardous, then and only then will we pull the recyclable materials from the load. By the time any material leaves our facility it has been processed and sorted by multiple people and machines.

If you were to ask everyone in opposition to this proposed monofill the following question: Do you support recycling? I would be shocked if you were to hear a single "No" answer. Recycling and Reuse of materials is becoming more popular and necessary every day. The proposed monofill would allow for recycling in the Mat-Su valley on a level that is currently not attainable. We don't recycle materials by the pound, we recycle them by the ton and we do so without being subsidized by the government. It would allow for reusable materials to be sold in the valley at a competitive rate and it would also open the valley up for the recycling of Construction and Demolition debris at competitive prices. In my experience if it costs someone more to recycle than it does to dispose of a material, generally they are not going to recycle it. It is irresponsible not to support a company that is willing to recycle materials that are not currently being recycled, especially when it doesn't cost an extra cent in taxes!!!!

The truth is, we are a good company that is run by good men, one of those being Shane Durand. We do a job that most are unwilling to do and we do it extremely well. I have heard some people say that the employees working for this company are untrained, that is completely false and unverified, the employees here are highly trained and knowledgeable regarding recycling and identifying hazardous materials. The opposition to this proposed monofill is based entirely on fear, not facts. The facts clearly show that we are capable of running a recycling facility and a monofill.

One of the largest gatherings in the state of Alaska is located across the street from an active monofill. Alaska Demolition's monofill is right next to the Alaska State Fair. How many Alaska State Fairs have been ruined by the monofill next to it?

This is a case of a few neighbors, who can't even see the proposed monofill from their homes, doing and saying whatever it takes to garner an emotional response from people who would otherwise take no interest in the proposed monofill. The majority are misinformed, some of my friends and family have been placed on a list of people who opposed the proposed monofill, without their consent or knowledge. "Where emotions run high, logic runs low" (Unknown). Please look past the emotions and the lies, and do the logical thing, support this proposed monofill based on the facts. Thank you for your time.

Subject: Central Monofill Services Conditional Use Permit

Hey, Susan,
I hope you're well. I just wanted to poke in and express support for the monofill CUP that CMS has requested. I got a mailer from some concerned neighbors about CMS' monofill app. It was pretty crazy so I thought I'd ask around a bit to see if this is something to take action about. I've learned over time that things are usually a little bit more complicated than the talking points on ANY flier. So this is what I've learned:

- Two other C&D monofills are within two miles of the proposed site. Neither of those facilities have the controls and processes in place that CMS proposes to reduce waste and monitor the waste for hazards. Neither of the other existing facilities has been shown to be a detriment to the community.
- There has been a similar monofill next to the State Fair for years. I've driven by it a number of times coming and going and it doesn't seem to be an issue. From what I know it has not contaminated the fair or the neighbors.

I get it, there's a lot of NIMBY that goes around and waste is an unpleasant topic. But I'd really like to see a stronger recycling presence here in the Valley. I feel like this monofill is a step in the right direction. I hope cooler heads prevail. Thanks for your time.

Best regards,
Peter House

Subject: Please support the Central Monofill Services Conditional Use Permit

Susan Lee,

I am a Palmer resident with young children living near the downtown area. We moved to this city because we appreciated it's unique history and it's potential for healthy growth. When I first learned about the proposed Conditional Use Permit for CRS, I was very skeptical and feared the negative affects it would have on our community. When I contacted the owner of CRS, he was very willing to discuss my concerns, encouraged me to visit the site and asks more questions, and provided information for me to continue researching on my own.

After doing so, I feel very strongly that this is a permit that would benefit our community far more than it would cause harm. Waste disposal is a part of living and CRS has been able to build a private business that successfully and responsibly recycles and disposes of our community waste.

Thank you for your time,

Rachel House

Subject: FW: Central Monofill Services Conditional Use Permit

My computer has been acting up and I'm Not sure if you received my email or not? So I decided to resend

To Susan Lee with MSB Development Services Division

Please support the Central Monofill Services Conditional Use Permit!

My name is Fred Thompson and have recently moved to 6301 E Birch Acre dr. Wasilla Alaska and previously lived on Lazy mountain for years.

I have lived in the Matsu area for the last 8 years and in Alaska since 1966 and support the Central Monofill Services Conditional Use Permit.

1) Central Monofill Services (CMS) along with Central Recycling Services (CRS) will be a great asset to the Matsu Borough (MSB) area to bring non subsidized Recycling to our Area.
2) CRS & CMS both private owned companies will bring additional employment to our MSB area along with additional Matsu Valley recycling not currently being offered.
3) Waste disposal facilities are a necessary part of living as we Americans produce substantial waste daily. Construction demolition of buildings and other structures generate massive amounts of debris that is deposited quite often in our public landfills along with other household and commercial garbage. CRS & CMS have ability to recycle then monofill the non-recyclable portion of waste material.
4) This service will extend the life of our public taxpayer backed landfills through private enterprise.
5) There have been other C&D Monofills in the same general area that are currently not recycling any of the materials and have not been a detriment to the local community. CMS through recycling processes will reduce waste and better monitor waste for hazards than other sites.
6) The CMS site is in a good location for the service they will bring to our area. It is well suited for truck and public traffic as it is in similar commercial area of other heavy truck traffic use from neighboring gravel pits.
7) CMS has been titled with trying to start a toxic waste dump and this could not be further from the truth. In fact they do not accept regular garbage type waste and additionally screen all product delivered to them by mechanical and hand process to further ensure the quality of their recycling products and finally the disposal of unused materials into the Monofill.
8) There seem to be a few people willing to say anything to stop this service being offered to the MSB but I hope with your investigation of this project you will see the truth and approval for the Central Monofill Conditional Use Permit.

Once again Please support the Central Monofill Services Conditional Use Permit!

Subject: Palmer dump proposal

Hello,

Please let me know an anchorage dump across the road from my property is not being seriously considered for at least one of many reasons.

-With all the open land available in AK, no reason whatsoever to pollute our backyard with so many variables and detrimental facts.

-The highway is already terrible with access and safety issues related to the gravel site and railroad.

-The proposed sight will almost certainly leach into the surrounding gravel bed depressions and also pollute the recreation areas and lakes surrounding the proposed site.

-Anchorage should be encouraged to handle their own waste... Barge to isolated area seems like a good option to me.

respectfully,

2650 S Skyranch Loop
Palmer, AK 99645

Subject: Public Comments on CMS 2014 CUP Application
Attachments: IMAG0513.jpg; IMAG0521.jpg; IMAG0503.jpg

Dear Susan Lee, The following are my comments and concerns regarding the 2014 C.U.P. Application by Central Monofill Services also known as CMS.

CMS a know and convicted polluter in the Mat-Su Borough (see below citations numbers) is once again requesting to establish a monofill dump within the boundaries of the Borough, on property that is an exhausted gravel extraction operation. The property in question was mined to water table, and the areas with commercial quantities of gravel remaining were dredged to bedrock creating open ponds in the water table. During the dredging operation a breach occurred in the local aquifer between two different levels of ground water requiring the State of Alaska DNR Dam Commission to become involved. At that time the operator of the gravel pit was required to establish a dam separating the two separate water levels. At the time of purchase of said property, a request to modify the existing dam with a spillway to relieve water levels only higher than historical normals was made to DNR. This modification was approved by DNR and the dam deregulated. Since that time the spillway modification has never stopped spilling. Water has continued to flow nonstop through the modification contrary to its intend design, and is suspected of causing water table irregularities in the area, as was the case during two previous breach events. DNR continues to insist that CMS repair the spillway to the original modification specifications and CMS refuses to act. Action pending by DNR.

3PA-13-03603MO
3PA-13-03604MO
3PA-13-03623MO
3PA-13-03601MO
3PA-13-03602MO
3PA-13-03624MO

During the year 2013 CMS applied for and was denied a C.U.P. for a monofill at this same location. Even before any permitting had been granted, CMS began Dumping garbage and construction debris, no State of Alaska permit, no Borough permit and no Borough business license. CMS's first argument was that it was there property and could do whatever they wanted to because the material they were dumping was not garbage but a product. A de-watering operation was also started, pumping garbage tainted water into the nearby open dredge ponds, again with no permit. The Borough's Code Compliance office issued orders to stop the activity and to remove the dumped garbage. CMS responded to this by covering it with a layer of dirt and told the Borough that it had removed the dumped material. CMS was found guilty in court on all charges brought against them by the Borough. CMS feels they are above the rules.

During the 2013 Planning commission hearing CMS swore up and down that they had the required 10' of separation from the water table as required by DEC at the lowest point in the gravel pit. This leads one to question, why if this was true, did the previous pit operator leave thousands of yards of easily recoverable gravel un-extracted? The fact is, the gravel was extracted, to just above water table and standing water existed on the property in several areas. Pictures taken during the ordered removal of the garbage dumped and covered with dirt by CMS show a process of painstaking and careful removal, that dis-spite their best efforts, reveal ground water seeping up and puddling at the removal site (see attached photos). CMS lied during their testimony to the Planning Commission and is in the process of amending their DEC application on this matter.

Just after CMS began their illegal dumping in the spring of 2013 several days of moderate to high winds occurred. This had the impact of depositing large amounts of wind blown garbage on, and littering adjacent private properties, not once but twice. To cover their activities and collective butts, a clean-up took place twice. CMS later argued in court that this blown trash had just blown through the site and collected over the winter much like garbage on and near the highway. May I note that in my 12 plus years living in this area, it was, and has been the only time this has occurred. CMS perjured themselves in court.

The Borough contracted a study by J.A. Munter Inc. Professional Hydrologist in February of 2014 regarding the possible effects of a monofill operation at this site. Unlike the cherry picked information submitted by CMS in their

application, this study should be required reading by the members of the planning commission, as it is likely to be much less biased.

The Municapaity of Anchorage and the borough both have facilities in place that can receive this type of waste, with tax revenue and oversight . Within the City of Palmer there already exsists a monofill dump not even half full. This facility has proven to have problems with the release of hydrogen sulfide gasses and underground fires. The need for this new facility only exsits for CMS to dump its trash so it can increase their bottom line. The potential problems that will occur at this site if permitted far outweigh any claims made by the applicant regarding minimal economic benefits. The Borough will not be receiving any significant tax revenue from this proposed activity, only future headaches.

Over the past decades we have, and continue to export gravel products out of the Borough to Anchorage with no tax revenue. The fact that we as a Borough, are even considering receiving in return their potentially polluting waste materials leads one to seriously question the mindset of Borough Government. CMS likes to push their message that this is all about recycling, but make no mistakes the end product of their operation is garbage, and this is a location poorly suited for this activity.

Thank You,
Richard Harbuck

Subject: Central Monofill Services land Use Permit comment

Central Monofill Services land Use Permit comment

I have attended two of the informational meetings by CMS and read the entire application for the conditional use permit. I urge you to please support the Central Monofill Services Conditional Use Permit.

Engine 557 Restoration Company has been a direct beneficiary of the recycling policy in place at Central Recycling Services. Construction materials such as shop doors, insulation, structural steel, industrial shelving and abatement services have all been provided through their program. Many of these items were salvaged materials saved from the trash stream.

This is a private company with no local, state or federal subsidy, prepared to relieve the local MSB land fills of thousands of tons of inert materials in a safe controlled manner. It is in every residents self interest to support this request, as without it cost to support the expansion of the MSB land fill will continue to increase. If you have not noticed, a small pickup load of household garbage less than 200 lbs, at the land fill just went from $8.00 to $11.00 this month.

It is long past time for the MSB to join the real world of materials management to include proper reclamation of recyclable products and internment of the remaining 25% of the stream that is inert. CMS is prepared to perform that service.

The resulting landscaped and developed property will certainly be an asset to the community compared to the gravel pit and the dust raising trespass activities that take place their now.

Long time resident,

Patrick J. Durand
4923 N. Kipling Dr.
Wasilla, Alaska 99654

Subject: Proposed monofill from CMS

To the Mat-Su Borough Planning Commission,
I'd like to express my deep concern and opposition to the proposed monofill at mile 38.3 Glenn Highway by CMS (Shane Durand). The proposed monofill would be disastrous for the Palmer and Gateway area.

Our well water has already been negatively impacted by the activities of Granite Construction when they pierced the aquifer in the proposed dump site. An independent well monitoring service tech told me "In thirty years' experience, I have never seen this much sediment in anything other than a freshly dug well, and even that usually settles within a day or two." Our neighborhood well has had this type of ongoing sediment for years, in spite of several layers of filters. The potential contaminants from ground-up construction debris, as well as potentially leaky discarded tanks and equipment, would leach directly into our well water and local lakes through this pierced aquifer and run-off, causing grave health concerns to residents near the area. I have raised 3 children here and know that they would be especially vulnerable to toxic contaminants such as lead, formaldehyde, arsenic, asbestos, fuel contaminants such as benzene, and more. I am rightfully fearful of the serious health consequences of exposure to toxins in household water.

Mr. Durand seems confident of his untrained and inexperienced abilities to secure asbestos-filled plastic bags with 100% accuracy while overseeing untold numbers of equally untrained and inexperienced subordinates. I, however, am highly doubtful. As you know, this is a high wind area where small debris and plastic bags are constantly blowing away and ripping to shreds in the wind. I have seen yard sized trampolines hanging from the treetops after windstorms. Residents here routinely lose roof shingles, lawn furniture, large trash cans, etc. in the wind and have to chase them down or retrieve them. This is NOT a good location for *any* dump, let alone one harboring contaminants like asbestos bagged in plastic. I come from a family who has extensive civilian contractor career experience in removing asbestos from defunct military sites all around Alaska. I know the level of safety precautions necessary as well as the ease in which untrained or unethical people can cause serious life affecting harm. Going off of recent actions, direct quotes, and facts, I personally believe that Shane Durand is not trained, trustworthy, accountable enough, nor credible enough to be handling this contaminant under his proposed circumstances.

Our family moved to this area with the understanding that the gravel pits would not be here forever, and that residential or park areas would be developed in the long run. It is family friendly, a good commuting location, and a clean and beautiful place. For the most part, the area is developing nicely and it is a desirable location for buying a home and living long term. Property values here have done well considering the widespread housing problems over the last several years. Adding a dangerous and unsightly dump right alongside the highway and adjoining our neighborhoods (and on top of our water), along with all the trucking, debris, and noise associated with it, is not good for Palmer. It's not good for our health, our environment, for the economic development of our town, nor for our property values. My husband and I have discussed our options and have decided that we will likely have to take a loss on our home and move if this dump is approved because of our health concerns for our children. One family moving may be of minimal concern to you as a board, however I urge you to consider that many others around us feel the same way- and we are hard working, productive, law abiding, healthy families that contribute to this area as consumers, business

owners, property tax payers, voters, and vested residents of Palmer, and we take good care of our properties. Please hear us and understand our concerns. I cannot imagine that Palmer would benefit from so many families leaving, and a dump and low-income, crime-ridden area developing as a result.

Thank you very much for your time and for hearing my concerns.

Sincerely,
Sarah Wolcoff

October 21, 2014

Matanuska-Susitna Borough
Development Services Division
Planning Department
350 East Dahlia Ave.
Palmer, Alaska 99645

Dear Susan Lee,

My name is Patricia Kepler Goossen. I am submitting this in protest of Central Monofill Services recent application for a conditional use permit. I would also like to file a complaint against recent activities by Central Monofill Services. I believe operations being conducted at the gravel pit located at MSB Tax Parcel #17N02E18C010 and #17N02E19B006 have had, and will have, a gross negative impact on my property and business. It is my understanding that the placement of a dam(s) in man-made industrial ponds at the gravel pit are causing increased pressure to the surrounding aquifer, resulting in a significant rise in water levels of nearby lakes and streams.

I own and operate Kepler Park, a campground located at Mile 37.4 Glenn Highway. Legal Description of property: #17N01E24B014. The property is situated on the shores of Kepler and Bradley Lakes. The nature of our business is to provide scenic camp/picnic sites and boat rentals to the public. I have serious concerns about the condition of our property and future of my business.

Areas of concern are:

1. Trees along shoreline: I have observed a drastic rise in water level of these lakes over the past two years and at an especially alarming rate during this past 2014 summer season! The water level has risen approximately one foot just since opening for business in May of this year! This was more than just the annual spring melt-off. The water level increased and continued to rise throughout the summer. The rise in water level has caused flooding of our campsites along the shoreline. Survival of trees along these shorelines are now threatened because of water surrounding them at their base and root systems. Some of these trees are over one hundred years old. Two trees have died and had to be removed as a result of this flooding. Grass and other vegetation which was on dry ground is under water and has been killed.
2. Camp/Picnic Sites: Also, as a result of this flooding, the shoreline is diminishing which reduces the amount of space required for our camp sites. One of our prime sites (#10 as pictured) has been reduced to one quarter of its original useable space. Two other sites have been reduced to half their original size. Four other sites along the shoreline are also being threatened by rising water levels.
3. Boat rentals: We provide boat rentals to the public for recreation and sport fishing in Kepler and Bradley Lakes. Customers have always had access to both lakes by way of a channel of water between them. A bridge spans this channel so it is necessary for boaters to float under it to access both lakes. The high water levels effect this part of our operations because there is no longer enough clearance under the bridge for boaters to pass through. Also, the launch area along the shore where our rental boats are parked has been reduced from a width of approximately 18 feet to now only 6 feet of useable space.
4. Bridge access: The bridge referred to is situated on a Matanuska-Susitna Borough designated roadway (Kepler Drive). The increasing water level is threatening the stability of the bridge abutments.
5. Fish/Wildlife: As mentioned, one aspect of our business is to provide access for sport fishing. Kepler and Bradley Lakes are stocked each year by the Alaska Department of Fish & Game. These lakes are fed by underground springs. It is already known that the materials disposed of in operations of a monofill dump site would result in the inevitable release of toxins into the ground water feeding these lakes. Such contaminants would threaten the lives of fish and water fowl. Also keep in mind that the fish in these lakes are used for human consumption.

We have been in business as a campground for 62 years. Many pictures have been taken over the years, including this year, so we have a visual comparison of the change in water levels. I am attaching copies of the most recent pictures taken this year.

It has been suggested that I seek legal counsel in this situation, for the killing of trees on our property and for property damages potentially resulting in loss of business. Hopefully, my protest and those of my neighboring property owners will be heeded, putting a stop to operations by Central Monofill Services at the proposed location. I would also hope that steps will be taken to reverse and correct the damaging effects the dams have had on the surrounding aquifer.

Thank you very much for your time and attention to this matter.

Sincerely,

Patricia Kepler Goossen

Subject: Central Recycling Services Conditional Use Permit

Dear Mat-Su Borough:

I would like to share my support for granting a Conditional Use Permit to Central Recycling Services which would allow them to permit their Central Monofill Services facility in the Valley. Besides the obvious aesthetic, economical, and health benefits of a cleaner Valley, it shows the Boroughs support for recycling. The exemplary history of the Company clearly shows it is both responsible and professional. We should be doing everything we can to ensure it will be in existence for years to come.

Subject: Palmer dump comment

I am writing to protest the recent permit application by CMS for a dump along the Glenn Highway in the middle of a complex watershed system. This watershed was already compromised by the previous owner of the site, which ran a gravel mining operation that cracked through the shale protecting the aquifer, which supplies water to several thousand homes. Nothing was ever done to fix this problem and the aquifer remains open to this day.

Now, CMS proposes an asbestos dump right there. The possibility for toxic leaching is very real, and there is NO WAY to fix contamination should it occur. Is the borough prepared to deal with a lawsuit from hundreds of homeowners? Is CMS prepared to deal with a lawsuit? Because I assure you, this is what would happen should thousands of families suddenly find their homes being supplied with poisonous water. Home values would drop like a stone, gutting the finances of those families. All because a for-profit, privately owned dump wants to put its trash in a place where it isn't regulated by the Mat-Su Borough, which has a very poor track record of protecting its own environmental concerns. I am writing to warn those on the planning commission to be aware of their own legacy. Do you really want to be remembered by future generations as one of the people who created the opportunity for environmental disaster?

Second to the issue of water quality is wind. Anyone who lives south of Palmer knows of the high winds that regularly occur. We have windstorms that last up to five days. Trash from the dump would blow everywhere. And what about the expansion of the Glenn Highway which will occur in 2016? The berms shielding the trash mountain from the road would be graded away, leaving a gigantic garbage heap visible to everyone who drives by.

Allowing this dump would give a whole new meaning to the term "Valley Trash" - indicative of a government that allows a toxic trash dump in plain sight of a main highway through Alaska, AND a moronic disregard of a water resource upon which thousands depend.

Let's not turn the Valley Trash nickname into truth.

To: Susan Lee
Subject: Central Monofill Services Conditional Use Permit

To Susan Lee with MSB Development Services Division

Please support the Central Monofill Services Conditional Use Permit!

My name is Fred Thompson and have recently moved to 6301 E Birch Acre dr. Wasilla Alaska and previously lived on Lazy mountain for years.

I have lived in the Matsu area for the last 8 years and in Alaska since 1966 and support the Central Monofill Services Conditional Use Permit.

1) Central Monofill Services (CMS) along with Central Recycling Services (CRS) will be a great asset to the Matsu Borough (MSB) area to bring non subsidized Recycling to our Area.

2) CRS & CMS both private owned companies will bring additional employment to our MSB area along with additional Matsu Valley recycling not currently being offered.

3) Waste disposal facilities are a necessary part of living as we Americans produce substantial waste daily. Construction demolition of buildings and other structures generate massive amounts of debris that is deposited quite often in our public landfills along with other household and commercial garbage. CRS & CMS have ability to recycle then monofill the non-recyclable portion of waste material.

4) This service will extend the life of our public taxpayer backed landfills through private enterprise.

5) There have been other C&D Monofills in the same general area that are currently not recycling any of the materials and have not been a detriment to the local community. CMS through recycling processes will reduce waste and better monitor waste for hazards than other sites.

6) The CMS site is in a good location for the service they will bring to our area. It is well suited for truck and public traffic as it is in similar commercial area of other heavy truck traffic use from neighboring gravel pits.

7) CMS has been titled with trying to start a toxic waste dump and this could not be further from the truth. In fact they do not accept regular garbage type waste and additionally screen all product delivered to them by mechanical and hand process to further ensure the quality of their recycling products and finally the disposal of unused materials into the Monofill.

8) There seem to be a few people willing to say anything to stop this service being offered to the MSB but I hope with your investigation of this project you will see the truth and approval for the Central Monofill Conditional Use Permit.

Once again Please support the Central Monofill Services Conditional Use Permit!

Subject: Attn: Susan Lee re: CMS monofill dump

I am writing concerning the proposed CMS monofill site just off the Glenn Highway at mile 38.3. After reviewing materials on the Borough website, including the Munter Report and the Planning Commission's June 2013 Resolution 13-30 which denied the permit, I continue to be adamantly opposed to this dump. In addition to that overwhelming evidence to deny this permit yet again (including the Planning Commission's own 37 "findings of fact and conclusions of law"), consider how this dump would be in direct violation of several goals of the Mat-Su Borough Core Area Comprehensive Plan--specifically Goals 1, 3, 7, and 8 ("Hazards: protect life and property from harm from natural and man-made hazards such as floods, erosion, wildfire, earthquakes, air and water pollution, and hazardous materials."). Furthermore, keep in mind that there already exists a dump site for construction waste (the Rebarchek Pit) just a couple of miles from the proposed CMS dump site. Not only is the proposed dump a hazard to the local residents and to the natural environment, it simply isn't necessary.

Please vote to deny their permit.

Subject: Stop private dumps

Dear Matanuska-Susitna Borough:

As a Palmer homeowner and business owner on a community well system, I am writing to oppose the permitting of private toxic dumps in the Borough. The CMS dump on Glenn Highway is five miles from our well, and a hydrology report after review of the conditional use permit has already shown that the dump has the potential to contaminate wells within one mile with hazardous waste from geologically unstable construction materials. What's to keep known carcinogens from traveling more widely in ground water, unbeknownst to the owners and the Borough?

Our homeowners' association has our communal water supply tested on an annual basis. If we start seeing the presence of or increases in creosote, lead, acrylic, chromium, pentachlorophenol, phenol-formaldehyde resins, cadmium, CVOCs, sulfate, hydrogen sulfide, arsenic, and other pollutants, will we have recourse against CMS? Your own Planning Commission Resolution 13-30 has already declared the site incompatible with the residential character of the area and the Borough's own land-use goals -- among other highly concerning violations of what a reasonable resident can expect in terms of protections by the Borough government. The site is less than a mile away from a major migratory bird refuge.

In addition, the decision to permit such an UNLINED dump site atop a drinking water aquifer (with no system in place to monitor leachate) is a flagrant violation of the public trust and our right to the protection of our health and safety. Why are public dumps, subject to oversight, insufficient to meet disposal needs?

Thank you for the opportunity to comment on this topic.

To: Susan Lee
Subject: Comments on CMS for Planning Commission Information Packet

My address is 2351 S Colleen St in Palmer, and my property is adjacent to the property on which CMS wants to run a monofill (Location MSB Tax Parcel# 17N02E18C010 and 17N02E19B006).

There are so many issues with them operating a monofill on this property. They include:

1. ASBESTOS - There is no independent inspection process to assure proper asbestos containment at this PRIVATELY OWNED, FOR PROFIT dump. The Palmer dump already has an asbestos cell and C&D (construction and demolition) section with proper oversight. AK Demo already runs a private C&D dump 2 miles away.

2. Poison Wells Up To a Mile From the Site - A borough sponsored hydrological evaluation concludes: "Contaminants could travel approximately a mile down-gradient and still exceed drinking water standards". A quote from CT.gov states, "wood waste from construction, renovation and demolition, pressure treated timber... may contain creosote, lead, acrylic, chromium, pentachlorophenol, phenol-formaldehyde resins, and other known carcinogens and ground water contaminants... These pollutants can leach into the ground water" (http://www.ct.gov/deep/cwp/view.asp?a=2718&q=325342)

3. Environmental Crime History - While being cited for ILLEGALLY DUMPING waste without a permit or even a business license, CMS Corporate Officer Shane Durand stated, "the solution to pollution is dilution." The company was later fined and were repeatedly ordered to clean up although they claimed the dump material was not trash. I personally took pictures of the trash that was blown onto other properties adjacent to this site and communicated directly with Mark Wisenhunt to have him come and see for himself the illegal activity of CMS. My wife also spoke directly with Shane Durand as he made false statements to the newspapers about "No Trespassing" signs I have on my property. To sum up his response to me, he explained that now she know how it feels to have false information spread to the papers. Therefore, he was okay with lying to the newspapers about us, because he felt that others were lying about him. Who would ever want a neighbor like that?!?!?!?!

4. Contamination of Fishing in the Kepler-Bradley Lake System - The site sits on top of the open aquifer that flows through fishing and recreation areas at Canoe Lake, Kepler-Bradley Lake, and beyond. Approval of a combination dump & junkyard permit for this property will allow fuel tanks and potentially leaky equipment to be parked on the edge of man-made gravel pit lakes OPEN TO THE AQUIFER.

5. Windblown Trash - "Valley Trash" WILL be what people see on their way to Palmer. That negatively affects tourism, business, property values, and tax revenues. I personally have witnessed this windblown trash already and they have not even been granted the legal permit to dispose of anything!

It is so disheartening that a company wants to destroy the beautiful area that I call my home. Please do not let them do this!!!!

Subject: Comments on CMS for Planning Commission Information Packet

My address is 2351 S Colleen St in Palmer, and my property is adjacent to the property on which CMS wants to run a monofill (Location MSB Tax Parcel# 17N02E18C010 and 17N02E19B006).

There are so many issues with them operating a monofill on this property. They include:

1. ASBESTOS - There is no independent inspection process to assure proper asbestos containment at this PRIVATELY OWNED, FOR PROFIT dump. The Palmer dump already has an asbestos cell and C&D (construction and demolition) section with proper oversight. AK Demo already runs a private C&D dump 2 miles away.

2. Poison Wells Up To a Mile From the Site - A borough sponsored hydrological evaluation concludes: "Contaminants could travel approximately a mile down-gradient and still exceed drinking water standards". A quote from CT.gov states, "wood waste from construction, renovation and demolition, pressure treated timber... may contain creosote, lead, acrylic, chromium, pentachlorophenol, phenol-formaldehyde resins, and other known carcinogens and ground water contaminants... These pollutants can leach into the ground water" (http://www.ct.gov/deep/cwp/view.asp?a=2718&q=325342)

3. Environmental Crime History - While being cited for ILLEGALLY DUMPING waste without a permit or even a business license, CMS Corporate Officer Shane Durand stated, "the solution to pollution is dilution." The company was later fined and were repeatedly ordered to clean up although they claimed the dump material was not trash. I personally took pictures of the trash that was blown onto other properties adjacent to this site and communicated directly with Mark Wisenhunt to have him come and see for himself the illegal activity of CMS. I also spoke directly with Shane Durand as he made false statements to the newspapers about "No Trespassing" signs I have on my property. To sum up his response to me, he explained that now I know how it feels to have false information spread to the papers. Therefore, he was okay with lying to the newspapers about me, because he felt that others were lying about him. Who would ever want a neighbor like that?!?!?!?!

4. Contamination of Fishing in the Kepler-Bradley Lake System - The site sits on top of the open aquifer that flows through fishing and recreation areas at Canoe Lake, Kepler-Bradley Lake, and beyond. Approval of a combination dump & junkyard permit for this property will allow fuel tanks and potentially leaky equipment to be parked on the edge of man-made gravel pit lakes OPEN TO THE AQUIFER.

5. Windblown Trash - "Valley Trash" WILL be what people see on their way to Palmer. That negatively affects tourism, business, property values, and tax revenues. I personally have witnessed this windblown trash already and they have not even been granted the legal permit to dispose of anything!

It is so disheartening that a company wants to destroy the beautiful area that I have called home for my entire life of over 35 years. Please do not let them do this!!!!

Subject: Proposed Monofill 2840 Glenn Hwy

Dear Ms. Lee,

I am writing as an Interested Party in the Central Monofill on 2840 Glenn Hwy. My home is down wind and down stream from the proposed dump and I am appalled that here we are again having to defend our homes. I thought we had settled this last year in June, but apparently Central Monofill has enough money to keep driving there plan through. I am offended that our public officials do not listen to the public voices on this issue. No still means no. I don't want a permanent dump polluting the water table where I get my well water from, nor do I want do live down wind of the stink and asbestos laden pollution the monofill will generate. I have not changed my mind since a year ago. I am categorically against the monofill because I want to live in a clean environment with clean water and air. Once you place a dump next too a neighborhood you have doomed that neighborhood to live with the effects of that dump forever! I urge the council to please consider the concerns of the home owners of the neighborhoods adjacent to the proposed dump.

Sincerely,

Rose Williams

Subject: Palmer Toxic Dumping Community Group

I am a landowner in Mountain View Estates off E. Outer Springer Loop. I am against the granting of a permit to CMS to open a private dump across the Glenn Highway from where I live. I worry about poisoning our water supply, trash blowing around from the site and pumping of contaminated water on wetlands. There is already a dump site on the Springer road system. We don't another one which won't have the proper oversight as the current dump. Thank you.

Subject: Kepler-Bradley Landfill

I'm writing to express my concern about a proposal by the CMC Corporation to open a private landfill in the Kepler-Bradley Lakes area. This area is both a bedroom community and an area that is popular with many types of recreation, and locating a landfill in this area is incompatible with current uses.

It is argued by CMC that because the landfill would consist of an unlined cell that only nontoxic material would be dumped there. However, as someone who has often visited the unlined C&D cell at the Mat-Su Borough landfill, I can attest that many toxic items end up in unlined cells. These toxic items, such as treated wood, painted wood, used carpet, and even lead/acid batteries, will eventually contaminate the ground water and surrounding lakes. It should be noted that when a dump contaminates ground water it basically does so forever. For example, ancient Roman dumps still produce leachate—fortunately, the leachate coming from these Roman dumps does not contain the toxic soup that will emanate from a dump that contains treated wood and other products of this modern age.

In addition to the inevitable contamination of the Kepler-Bradley Lakes area water, a landfill at this location will also contaminate the air and landscape. This is a very windy area, and even the best effort to contain and cover dumped material before it blows away is an impossible task. Again, an examination of the area surrounding the Mat-Su Borough landfill provides ample evidence: blown garbage of all kinds covers the surrounding area despite the fact that the landfill staff works to cover the garbage as quickly as it is dumped.

Finally, allowing a private corporation to install a potentially toxic dump is inviting a future liability for Borough tax payers. A dump such as the one that CMC is proposing is similar to a mine that produces toxic material. Mining companies typically abandon old mines and declare bankruptcy once the resource has paid out. Once this proposed dump is filled, CMC will have no incentive to maintain the dump in perpetuity because doing so would cost much more than any bond that the company may have put up upon permitting. The tax payers of the Mat-Su Borough (and perhaps the state government) will be left to clean up any pollution. Moreover, CMC's track record as a polluter does not instill confidence that it will do the right thing and continue to monitor and clean up any pollution coming from their proposed dump site. Thus, I urge you to deny this permit. Let CMC find another location that will not threaten area ground water and that is not in such a windy area.

FIRST CLASS MAIL

The Matanuska-Susitna Borough Planning Commission will consider the following:
Application or Item: *Application for a conditional use permit for the operation of a monofill for the disposal of inert material*
Matanuska-Susitna Borough Code Section: MSB 17.60 – Conditional Uses
Applicant: Central Monofill Services 99645*0097 B001
Request: *An application has been submitted for the operation of a monofill for the disposal of inert material. The inert debris will primarily be non-hazardous shredded residual, non-recyclable waste material from construction and demolition waste. Regulation Asbestos Containing Material (RACM) and Non-RACM will also be accepted at the monofill site.*
Location: MSB Tax Parcel# 17N02E18C010 (2840 S. Glenn Hwy.) and 17N02E19B006 (2560 S. Glenn Hwy.); within Township 17 North, Range 2 East, Sections 18 & 19, Seward Meridian.

The Planning Commission will conduct a public hearing in the Borough Assembly Chambers, Palmer, Alaska, on this item on ***December 1, 2014***. The meeting begins at 6:00 p.m. ***Public hearings begin at 6:15 p.m.*** This may be the only presentation of this item before the Planning Commission and you are invited to attend.

This conditional use permit application will be introduced for public hearing at the **November 3, 2014** Planning Commission meeting. The Planning Commission members may submit questions to the Planning Commission Clerk concerning the matter or request for more information from the applicant at the time of the introduction. All questions and requests submitted by the Commission shall be in writing and copies will be provided to the applicant and made available to all interested parties and the public upon request. Answers to questions and additional material requests will be addressed in the staff report for the public hearing.

Commission members may not receive or engage in ex-parte contact with the applicant, other parties interested in the application, or members of the public concerning the application or issues presented in the application.

Application material may be viewed on-line at www.matsugov.us and clicking on 'Public Notices'. Application material may also be reviewed in the Borough Permit Center. If you have any questions or, would like to send us comments, concerning the proposed action, this form may be used for your convenience by filling in the information below and mailing it to the Matanuska-Susitna Borough, Development Services Division, Planning Department, 350 East Dahlia, Palmer, Alaska 99645. You may fax comments to 861-7876 or e-mail to *slee@matsugov.us*. For additional information please contact Susan Lee, Planner II, at 861-7862. Comments received by ***5 p.m., October 31, 2014*** will be included in the Planning Commission packet for the Commissioner's review and information. Please be advised that comments received from the public after that date will not be included in the staff report to the Planning Commission but will be provided as hand-outs to the Commission. If there is not enough room below, please attach this sheet to another piece of paper. **In order to be eligible to file an appeal from a decision of the Planning Commission, a person must be designated an *interested party*. See MSB 15.39.010 for definition of *"Interested Party"*. The procedures governing appeals to the Board of Adjustment and Appeals are contained in MSB 15.39.010-250, which is available on the Borough internet home page, (http://www.matsugov.us), in the Borough Clerk's office, or at various libraries within the borough.**

Comments:

We are 100% against allowing any type of waste debris being dumped in the proposed site, no matter how safe it is suppose to be. There would be no monitoring of the water from our well to assure that we are not drinking toxic waste that is leaking from the waste debris. The lakes are also at risk of toxic leaks, who safe guards the fish that live in the lakes? Again, we are 100% against any type of waste debris being dumped.

Once the water table is contaminated there is no turning back!

Susan Lee

Development Services
OCT 23 2014
RECEIVED

Dear Susan Lee,

My name is Patricia Kepler Goossen. I am submitting this in protest of Central Monofill Services recent application for a conditional use permit. I would also like to file a complaint against recent activities by Central Monofill Services. I believe operations being conducted at the gravel pit located at MSB Tax Parcel #17N02E18C010 and #17N02E19B006 have had, and will have, a gross negative impact on my property and business. It is my understanding that the placement of a dam(s) in man-made industrial ponds at the gravel pit are causing increased pressure to the surrounding aquifer, resulting in a significant rise in water levels of nearby lakes and streams.

I own and operate Kepler Park, a campground located at Mile 37.4 Glenn Highway. Legal Description of property: #17N01E24B014. The property is situated on the shores of Kepler and Bradley Lakes. The nature of our business is to provide scenic camp/picnic sites and boat rentals to the public. I have serious concerns about the condition of our property and future of my business.

Areas of concern are:

1) Trees along shoreline: I have observed a drastic rise in water level of these lakes over the past two years and at an especially alarming rate during this past 2014 summer season! The water level has risen approximately one foot just since opening for business in May of this year! This was more than just the annual spring melt-off. The water level increased and continued to rise throughout the summer. The rise in water level has caused flooding of our campsites along the shoreline. Survival of trees along these shorelines are now threatened because of water surrounding them at their base and root systems. Some of these trees are over one hundred years old. Two trees have died and had to be removed as a result of this flooding. Grass and other vegetation which was on dry ground is under water and has been killed.
2) Camp/Picnic Sites: Also, as a result of this flooding, the shoreline is diminishing which reduces the amount of space required for our camp sites. One of our prime sites (#10 as pictured) has been reduced to one quarter of its original useable space. Two other sites have been reduced to half their original size. Four other sites along the shoreline are also being threatened by rising water levels.
3) Boat rentals: We provide boat rentals to the public for recreation and sport fishing in Kepler and Bradley Lakes. Customers have always had access to both lakes by way of a channel of water between them. A bridge spans this channel so it is necessary for boaters to float under it to access both lakes. The high water levels effect this part of our operations because there is no longer enough clearance under the bridge for boaters to pass through. Also, the launch area along the shore where our rental boats are parked has been reduced from a width of approximately 18 feet to now only 6 feet of useable space.

4) Bridge access: The bridge referred to is situated on a Matanuska-Susitna Borough designated roadway (Kepler Drive). The increasing water level is threatening the stability of the bridge abutments.
5) Fish/Wildlife: As mentioned, one aspect of our business is to provide access for sport fishing. Kepler and Bradley Lakes are stocked each year by the Alaska Department of Fish & Game. These lakes are fed by underground springs. It is already known that the materials disposed of in operations of a monofill dump site would result in the inevitable release of toxins into the ground water feeding these lakes. Such contaminants would threaten the lives of fish and water fowl. Also keep in mind that the fish in these lakes are used for human consumption.

We have been in business as a campground for 62 years. Many pictures have been taken over the years, including this year, so we have a visual comparison of the change in water levels. I am attaching copies of the most recent pictures taken this year.

It has been suggested that I seek legal counsel in this situation, for the killing of trees on our property and for property damages potentially resulting in loss of business. Hopefully, my protest and those of my neighboring property owners will be heeded, putting a stop to operations by Central Monofill Services at the proposed location. I would also hope that steps will be taken to reverse and correct the damaging effects the dams have had on the surrounding aquifer.

Thank you very much for your time and attention to this matter.

Sincerely,
Patricia K Goossen

Subject: CRS valley project coments

I am in favor of the Monofill and the efforts CRS has made to get this project going. I have seen the site in Salcha and it is a clean area of work. There are no birds, animals or stench that goes along with many other waste sites Ive seen over the years. Costruction Debris that has been processed is What I refer to as clean trash. Its gotta go somewhere and they do a fine job with it.

Subject: Monofil permit

I am writing to express my concerns about the re-application for the Monofil Dump Site. Having lived in the State 56 years, I have seen a lot of changes take place. Some good, some not so good. I have lived in the Valley for 31 years. I have enjoyed the beauty and pristine environment of both the Butte and now the Springer System area. This Dump Site does not comply with anything worthwhile in the continuation of preserving or protecting this area. My main concern is the existing watershed. Due to the lack of monitoring of the contents which will be "dumped and buried" at this proposed site, this leaves our precious water open to extreme pollution. During the last permitting application process the Borough's Staff found several reasons why this is NOT a good venture. Please, please do not allow this application to be permitted! Thank you.

Sincerely,
Sandra Duncan

Subject: Please deny the permit request for the monofil dump in Palmer, AK
Attachments: W-Mat-Su-Borough-Denies-Permit_June2013.pdf

Hello,

I would first like to start out with a thank you to the borough for denying the first permit application and protecting my family for the extremely negative affects of having a toxic dump in our back yard. I have four children who have grown up in Palmer in our house in Mountain View Estates, this is our home and it is beautiful. Our community well is at risk of being contaminated, our beautiful landscape is at risk of being turned into a trash strewn mess and our wildlife will be pushed even further from their natural habitat. We have fish beds that will be fed with toxins from the dump, children will be drinking contaminated water! Please consider the facts below when this permit comes up on your docket-

The site sits on top of the massive aquifer that feeds our lakes and provides drinking water. A dump permit would allow tanks and potentially leaky equipment to be parked next to the ponds open to the aquifer. **Large fuel tanks are already reportedly on site.** Accidents happen.

ASBESTOS, HEALTH CONCERNS, AND PROPERTY VALUES

The dump owners say that Asbestos will only be delivered in plastic bags, so it will never be a problem. The community with neighbors as close as 500 feet from the dumpsite are being asked to believe that accidents never happen. No contractor or busy demolition worker will ever make a mistake, mix up the paperwork or misunderstand instructions. Accidental asbestos contamination to some degree seems highly probable, yet the company assures us that this very legitimate worry will not affect anyone's property values.

WELL CONTAMINATION IS PREDICTED

The 2014 Munter Report on hydrology studied the specifics of the dump's site operation plan and concluded that the **site may contaminate wells up to 1 mile away.**

WATER CONTAMINATION & HISTORY OF ILLEGAL DUMPING

Dump management have shown no concern about pumping contaminated surface runoff into the ponds. In fact, while being cited for illegally dumping waste without a permit, **Shane Durand stated to the borough official, "the solution to pollution is dilution."** (MSB Code compliance case summary G20130022 page 5—see the official Borough Citations.

Neighbors whose groundwater is being polluted would disagree with Mr. Durand; the Solution to Pollution is PREVENTION.

WINDBLOWN TRASH

The dump's owners say the 60 MPH wind won't be a problem. They have said that they believe that stacks of tires and the trees on neighboring property will keep debris from leaving the site. Neighbors are pretty sure this dump will end up being spread for miles up and down the Glenn Highway into Palmer. **"Valley Trash" *will* be what people see on their way to Palmer.**

Thanks for your consideration,

Amber Reed

Palmer, AK 99645

MATANUSKA-SUSITNA BOROUGH
PLANNING COMMISSION RESOLUTION NO. 13-30 (Am)

A RESOLUTION OF THE MATANUSKA-SUSITNA BOROUGH PLANNING COMMISSION ADOPTING FINDINGS OF FACT AND CONCLUSIONS TO SUPPORT THEIR FAILURE TO APPROVE RESOLUTION 13-22.

WHEREAS, Resolution 13-22 recommended approval of a conditional use permit for the operation by Central Monofill Services (CMS) of an inert material monofill on parcels 17N02E18C010 and 17N02E19B006, within Township 17 North, Range 2 East, Sections 18 and 19, Seward Meridian; and

WHEREAS, Resolution 13-30 contains findings of fact and conclusions of law which support denial of the conditional use permit; and

WHEREAS, on June 3, 2013, the Planning Commission held a public hearing on Resolution 13-22; and

WHEREAS, the Planning Commission's vote on the motion failed to garner a majority vote on June 3, 2013; and

NOW, THEREFORE, BE IT RESOLVED, that the Matanuska-Susitna Borough Planning Commission denied the conditional use permit based on the following findings of fact and conclusions of law:

1. Borough staff has documented trash and the Daily Cover (screened fines) that have blown from the monofill onto adjacent properties.

2. Borough staff has documented trash and/or the Daily Cover blown over the 40 foot hill on the west side of the property.

3. ADEC regulations (18 AAC 60.420(2)) states a monofill must be operated so that litter is controlled by fencing or another approved means, and is removed from access roadways and other areas in the facility.

4. This region experiences frequent multiple-day high-wind events each year since it is at the confluence of the Matanuska and Knik River valleys. Loose debris and dust from the fill has and is expected to continue to scatter beyond the boundaries of the site.

5. Fencing is not expected to contain the trash and/or the Daily Cover/screened fines on the site. The trash and/or Daily Cover/screened fines will get blown into the trees and surrounding properties.

6. CMS has not provided adequate mitigation plans for preventing trash and debris from leaving the site.

7. The Daily Cover/screened fines consist of shredded materials that are less than two inches in size. Material this size is easily distributed by the wind.

8. The inert debris that will be deposited on the site will be shredded into pieces 12 inches or smaller. Material this size can also become windblown.

9. The previous use of this site was for earth materials extraction. There are pre-existing legal nonconforming use rights for earth materials extraction for this property, which means that the industrial use was not approved under the current regulatory structure or evaluated for compatibility with surrounding land uses.

10. The proposed monofill is an industrial use and is an incompatible use with the surrounding residential areas as it cannot be completely screened from the surrounding residences to the west, debris from the monofill will blow onto the surrounding residences and roadways, and there is the possibility of contamination of drinking water wells in the area.

11. The final height of the monofill is proposed to be at 150 feet above sea level (ASL). The proposed monofill will have 2700 feet of frontage along the Glenn Highway. The proposed completed height of the monofill will be 35 to 40 feet above the adjacent berms on the southwest perimeter of the site.

12. The monofill will be unsightly from the Glenn Highway, and from the surrounding properties, including the residential subdivision directly to the west. It is not possible to completely screen the monofill because of topography and because the project is proposed to be 150 feet (ASL) high at completion.

13. The proposed monofill is inconsistent with some of the land use goals and policies of the Borough-Wide Comprehensive Plan (2005 Update) and the monofill is an industrial use and incompatible with the neighboring residential areas.

14. The proposed monofill is inconsistent with some of the goals and policies of the Borough-Wide Comprehensive Plan (2005 Update) and the Core Area Comprehensive Plan (2007) as there is the potential for groundwater contamination that could have negative effects on drinking water and surface water quality.

15. The proposed monofill is inconsistent with the goals and policies of the Borough-Wide Comprehensive Plan (2005 Update) and the Core Area Comprehensive Plan (2007 Update)

16. The proposed monofill will not preserve and will detract from the value, character, and integrity of the surrounding area as the monofill will be unsightly from the Glenn Highway and from the surrounding properties including the residential subdivision directly to the west. It is not possible to completely screen the monofill because of topography and because the project is proposed to be 150 feet (ASL) high at completion. Conditions may be set to address trash and debris containment on the site (17.60.100(B)(1)).

17. Comments received regarding the proposed monofill raised the following concerns:
    - Dumping of material without MSB or ADEC permits.

- Dumping of hazardous waste
- Trash in the water
- Water pollution
- Health problems
- Pollution of surrounding lakes
- Protection of watershed and aquifer
- Compromising the aquifer
- Windblown unhealthy dust and particulates from the monofill
- Pollution of drinking water
- Windblown materials/debris onto surrounding properties
- Impact on downstream waterways
- Long term safety of water quality
- Contamination of water table
- Use the existing landfill for disposal of material
- Previous problems with gravel extraction on this property and rising water table
- Trash in the trees is an eyesore
- Breaching of berm between two of the manmade lakes and impact on surrounding water levels
- Long term impact of contamination of drinking water
- Disregard for lakes, streams, and drinking water
- Lack of oversight and planning
- Lack of CMS's ability to manage and provide oversight of the facility
- Concerns about reclamation of the property
- Dumping of garbage/monofill near standing water
- High wind area will cover surrounding area with dust and debris from monofill
- Contamination of soil
- Residents are entitled to clean air, land and water
- Lowering of property values
- The Glenn Highway is a Scenic Byway
- Threat to migratory and breeding birds
- How the redesign of the Glenn Highway will affect this site

- Rising water level of Canoe Lake due to dam breach
- Concerns about asbestos being dumped at this site
- Concerns about lead based paint, mercury and heavy metals deposited in the monofill
- Too close to residential area

18. The monofill will be unlined.

19. Materials brought to the site will not be deposited on an impermeable surface that will contain any prohibited and/or contaminated materials.

20. No system is proposed to capture, treat, or monitor leachate leaving the site.

21. Alaska Department of Environmental Conservation (ADEC) regulations state that an unlined landfill may not be located closer than 10 feet above the highest measured level of an aquifer of resource value unless the landfill is constructed two feet or more above the natural ground surface (18 AAC 60.217).

22. The applicant has not addressed how they will monitor or manage the seasonal high water table fluctuations to ensure that the bottom of the monofill is not annually saturated by groundwater.

23. Soils in the area of the monofill site are very porous, loose gravels and glacial loess, and offer little or no filtering capacity for fluids being emitted or drained from the fill. Without a liner, a ten foot separation is not sufficient to prevent leachate from reaching the water table increasing the risk of potential contamination of the water resources in the area.

24. Contaminants typically found in groundwater surrounding construction and demolition landfills include cadmium, lead, iron, manganese, several chlorinated volatile organic compounds, sulfate, hydrogen sulfide, and TDS (Total Dissolved Solids). Chromium and arsenic are found if chrominated copper arsenate-treated wood is disposed in the landfill.

25. The site appears to be up gradient of the groundwater flow direction from private drinking water wells. Without a Fate and Transport Model for compounds of concern to evaluate the risk posed by the proposed monofill to down gradient wells, there is no way to evaluate if these compounds will reach the drinking water wells at concentrations posing risk to health.

26. Baseline data for water quality has not been provided.

27. Seasonal water table elevation fluctuations have not been established.

28. The top of the completed monofill drops 40 feet from one end to the other. The run-off from this slope could pose problems with the dredge ponds at the base of the monofill causing problems with the aquifer.

29. Migratory birds, especially waterfowl, are attracted to the ponds already on the site. Material used as daily cover includes material potentially hazardous to birds if ingested.

30. This site is less than one mile from the Palmer Hay Flats Refuge, which is the major migratory bird refuge in Southcentral Alaska.

31. It is not possible to set conditions to adequately protect the groundwater and aquifer from anticipated negative effects of the monofill. The stormwater management proposed by the applicant will maximize the volume of water infiltrating the monofill. This infiltrating meltwater and rainfall will percolate through the placed materials, enter the groundwater and a large unconfined aquifer. The leachate from the construction and debris monofill may contain compounds at concentrations above drinking water standards. That water will impact private and public water wells used by homes, neighborhoods and farms, and could also enter nearby lakes that are heavily used. Adequate baseline water quality data monitoring to establish the quality of the existing water, the level of the groundwater throughout the monofill site, and the porosity of the materials under the monofill, has not been provided.

32. The proposed monofill will be harmful to the public health, safety, convenience, and welfare (17.60.100(B)(2)).

33. The site plan depicts the proposed structures in compliance with setback requirements.

34. The application minimally addresses the impacts of the climate, geology, hydrology and geography of the site and the impacts to surrounding land uses.

35. According to documentation and studies the proposed monofill site is located where the topography, geology, hydrology and soil are inadequate for protection of ground and surface water quality.

36. The conditional use does not fulfill all other requirements of this chapter (17.60.100(B)(4)).

37. The berm adjacent to the Glenn Highway will have to extend in height in order to obscure the view of the monofill from the highway.

BE IT FUTHER RESOLVED that this is a final determination which may be appealed in accordance with MSB 15.39.140 by filing a written notice of appeal with the Borough Clerk within 21 days from the date this determination was issued. If an appeal is not filed as described in the preceding sentence, the right to appeal is forfeited.

ADOPTED by the Matanuska-Susitna Borough Planning Commission this 17th day of June, 2013.

JOHN KLAPPERICH, Chair

Subject: Please STOP the Monofill Project

To Whom it may concern,
I am against the proposed Monofill. The highway does not need the additional large truck traffic on a stretch of road that is already congested. This is a state thoroughfare depended on by heavy commuter traffic as well as tourists in the summer months. Why would anyone consider adding additional heavy truck traffic, pulling on and off the highway, to such an import transportation route. POOR LOCATION.
Thank you,
Ron Richards

Subject: MONOFILL

I am writing about the monfil project just off the Glenn Highway – behind the gun club. I live in Mt View Subdivision and we share a community well. Our water depth is very shallow and contamination of the water basin is a huge concern to all of us. Can this company guarantee clean water? Also, what will happen if the water is contaminated ? Another concern is appearances – this is a dump that people will see from the highway – is this the way we want to present the most beautiful spot in Alaska? When is there going to be an meeting about this ? I want to put it on my calendar – Thanks for reading this.....

Subject: Toxic Waste dump/ monofil

I live in the Mountain View Estates subdivision not far from the proposed proposed toxic waste dump/ monofil. I oppose the borough granting a permit for this facility as toxins will get into the water table sooner or later,our strong winds will carry debris onto private property and also degrade our air quality. Additionally, the dump will be an eye sore to all who drive to Palmer on the Glenn Highway. As a member of the tax paying public, I strongly request and advise the MSB to hold well advertised public meetings prior to action on this proposed dump. Any other action is irresponsible and not in the public interest. Thank you.

Subject: Public Comment - CMS Monofill in Palmer

I strongly urge the Borough Planning Commission to deny any type of permit to Central Monofill Services that creates a dump on parcels 17N02E18C010 and 17N02E19B006 within Township 17 North,, Range 2 East, Sections 18 and 19, Seward Meridian.

The findings of fact and conclusions of law stated in Matanuska-Susitna Borough Planning Commission Resolution 13-30 should be more than enough reason to again deny this permit. Add to that the three citations issued to CMS for failing to comply with a cleanup order, dumping trash that created a public nuisance, and operating a junkyard without a permit.

There is compelling reason to deny this permit. Being a resident of Palmer, I do not want this unsightly development, that could very possibly contaminate lakes and aquifers, and most assuredly have blown trash littering neighborhoods and streets, permitted to move forward.

Thank you.

OCT 22 2014
RECEIVED

The Matanuska-Susitna Borough Planning Commission will consider the following:

Application or Item: *Application for a conditional use permit for the operation of a monofill for the disposal of inert material*

Matanuska-Susitna Borough Code Section: MSB 17.60 – Conditional Uses

Applicant: Central Monofill Services 99645#2901 B039

Request: *An application has been submitted for the operation of a monofill for the disposal of inert material. The inert debris will primarily be non-hazardous shredded residual, non-recyclable waste material from construction and demolition waste. Regulation Asbestos Containing Material (RACM) and Non-RACM will also be accepted at the monofill site.*

Location: MSB Tax Parcel# 17N02E18C010 (2840 S. Glenn Hwy.) and 17N02E19B006 (2560 S. Glenn Hwy.); within Township 17 North, Range 2 East, Sections 18 & 19, Seward Meridian.

The Planning Commission will conduct a public hearing in the Borough Assembly Chambers, Palmer, Alaska, on this item on ***December 1, 2014***. The meeting begins at 6:00 p.m. ***Public hearings begin at 6:15 p.m.*** This may be the only presentation of this item before the Planning Commission and you are invited to attend.

This conditional use permit application will be introduced for public hearing at the **November 3, 2014** Planning Commission meeting. The Planning Commission members may submit questions to the Planning Commission Clerk concerning the matter or request for more information from the applicant at the time of the introduction. All questions and requests submitted by the Commission shall be in writing and copies will be provided to the applicant and made available to all interested parties and the public upon request. Answers to questions and additional material requests will be addressed in the staff report for the public hearing.

Commission members may not receive or engage in ex-parte contact with the applicant, other parties interested in the application, or members of the public concerning the application or issues presented in the application.

Application material may be viewed on-line at www.matsugov.us and clicking on 'Public Notices'. Application material may also be reviewed in the Borough Permit Center. If you have any questions or, would like to send us comments, concerning the proposed action, this form may be used for your convenience by filling in the information below and mailing it to the Matanuska-Susitna Borough, Development Services Division, Planning Department, 350 East Dahlia, Palmer, Alaska 99645. You may fax comments to 861-7876 or e-mail to *slee@matsugov.us*. For additional information please contact Susan Lee, Planner II, at 861-7862. Comments received by ***5 p.m., October 31, 2014*** will be included in the Planning Commission packet for the Commissioner's review and information. Please be advised that comments received from the public after that date will not be included in the staff report to the Planning Commission but will be provided as hand-outs to the Commission. If there is not enough room below, please attach this sheet to another piece of paper. **In order to be eligible to file an appeal from a decision of the Planning Commission, a person must be designated an *interested party*. See MSB 15.39.010 for definition of *"Interested Party"*. The procedures governing appeals to the Board of Adjustment and Appeals are contained in MSB 15.39.010-250, which is available on the Borough internet home page, (http://www.matsugov.us), in the Borough Clerk's office, or at various libraries within the borough.**

Comments: The Kepler family owns part of Kepler Lake, Bradley Lake, and Echo Lake. We own all of Harriet Lake. The water level has gone up a foot plus in the last couple of years. This last winter was one of the driest on record and the water level continued to go up. Kepler Park is flooding. You can not take a boat under the bridge and the pizza sites and boat launch areas are diminishing in size. Our water level is a function of what goes on in the gravel pits. The trees along the edge of the water provide wildlife. (I have pictures Enclosed.)

Subject: Response to Central Monofill Application

I am writing in response to the Central Monofill Application.

I live in the Kepler Bradley Lakes area, a pristine Matanuska Valley location surrounded by recreational and private lakes abundant with wildlife. It is also home to many of my dear neighbors.

I DO NOT want Central Monofill in my "back yard."

I do not want non-recyclable construction materials, asbestos, demolition waste, shredded residual waste, nor any other hazardous and non-hazardous waste dumped in my "back yard."

I do not want hazardous and non-hazardous residuals leaching into my water well, and recreational waters. The health risks are too great.

I do not want noise pollution caused by machinery and the many vehicles traveling in and out of Central Monofill, nor debris strewn across the landscape.

What I DO want is that my family live without fear of serious health problems caused by Central Monofill.

The Mat-Su Convention and Visitors Bureau recently celebrated the land purchase for a new Gateway Visitor Center, located at Mile 36, Glenn Highway, on June 6, 2014. The Center will provide shopping, sightseeing, and recreational use information to Alaska residents and tourists. It will boost our economy. This major project is to protect the scenic qualities along the ENTIRE length of the Glenn Highway, and that includes subject parcels 17N02E18C010 and 17N02E19B006.

To approve the Central Monofill application will bring a whole new meaning to "Valley Trash."

Please, for the health and peace of mind of Valley residents, and in preserving our scenic natural beauty, DO NOT approve the Central Monofill application.

I will be attending the public hearings on November 3, and December 1, 2014.

Respectfully submitted,

Elaine (Lainie) Karisko

Subject: Toxic Dumping

Since we live in the area, we feel that there should be no private toxic wast dumps in this area. Our children fish all year on the lakes in this area. The Kepler-Bradley Lake system is one that families need to continue to enjoy for years to come. As protectors of the land we need to make sure that what we give vote to now is a good thing, not a passing fancy that will satisfy us for a few years, but turn around and be harmful for our children and grandchildren.
There is space in Alaska for a toxic dump to operate safely. It may appear to be more costly to companies and taxpayers at the moment, but in the future it will be money well spent.

Illegal dumping of toxic and non-toxic dumping is a problem in the valley and it must be brought to the attention of all. The brough must stop this permit that has been "tentatively approved" by the DEC. We as the residents need to know that our borough government is doing all in thier power to keep our lands, water and people protected from this unhealthy dump site.

Hi,
DO NOT issue a permit to CMS for a private dump. This case is a good example of why the Borough needs to tighten their dumping code!

Please publicize the names of the assemblymen who vote to issue a permit, so we know who **NOT** to vote for in future elections!

Thank you for giving me the opportunity to voice my opinion,
Dorothy Durfee

To: Susan Lee
Subject: Dump

It never ceases to amaze me that it is the year 2014 and yet we have people who are suppose to be representing and enforcing the laws of the land that think we are in the old west and it's the 1800's. That want to relive the era when immigrants in this country were brought over and forced to work for meager wages or none and were shot if they stepped out of line. We hear how the land was stolen from the native people in the old west so the rich rancher could expand his holdings and make life better for those of us that toed the line, kept their mouth shut and allowed a hand full of degenerates to take over the country and do what ever they dam well pleased. Wait that's a movie or is it.

Today 2014 we are facing that mentally. Not any more sophisticated than the 1800, just a little more so called political correct, at least that is what you would have us believe and you know how stupid and dump the American people are.

You are suppose to be our friends, our neighbors, but you act more like the cattle barons of the old west, except this time it is still land that you want. Land that you want to ruin and pollute for whatever you think your cattle baron wants to take.

The idea of a dump of this nature that the bough and our so called representatives want allow at the convenient site for the master who will reward you with what you think is good money and will leave us with our own private toxic environment in years to come. Iam a little familiar with these harmless dumps scattered throughout the old military bases in Alaska and believe me they turned out to not be clean and non-toxic as they were thought to be. MONEY was the reason that the land out there is/was an environmental nightmare. We are talking just harmless building products, asbestos, paints, old furniture and brand new furniture, you know the harmless types of products that are perfectly safe until bury them into the ground or burn them, well I hope you people are bright enough to understand what I am saying.

I am not against progress or the development of new resource. I think that people who think the idea of the coal production is a killer, but the glacial silt we breath and shovel out of the house after a good wind is not harmful, but I know that we can not fight mother nature. Introducing products that will have a deadly effect on the community over an extended period of time, we can fight. I am sure that some one in Borough must realize that we have 25,260 sq. miles here, so why take an residential area and allow it to be ruined, this is not an "not in my back yard" protest, because I do not want it in anyone's else's back yard.

I am not against a dump away from living area or potential new living areas so some cattle baron can collect his money at the least expense or the easiest convenience for his company. You are willing to take what ever meager money these people going to offer you to ruin the lives of the young people who will be raised under these circumstances and in the name of it's the interest to the borough. We have enough stupid people now.

You folks can try to call it a low impact dump, I know better because I have been on enough clean up jobs in the bush and Aleutians to know better. I just can not believe the EPA would allow this site unless they were/are given incorrect facts. I ask you to send this outfit down to a site that exist and charge their customers more to transport it, just like I have to do every time I go into any store and prices have increased almost daily because of transportation cost and you will still get your tariff . Thank you for taking my comments and hope to meet the group who will be making the decision

Request: *An application has been submitted for the operation of a monofill for the disposal of inert material. The inert debris will primarily be non-hazardous shredded residual, non-recyclable waste material from construction and demolition waste. Regulation Asbestos Containing Material (RACM) and Non-RACM will also be accepted at the monofill site.*

Location: MSB Tax Parcel# 17N02E18C010 (2840 S. Glenn Hwy.) and 17N02E19B006 (2560 S. Glenn Hwy.); within Township 17 North, Range 2 East, Sections 18 & 19, Seward Meridian.

The Planning Commission will conduct a public hearing in the Borough Assembly Chambers, Palmer, Alaska, on this item on ***December 1, 2014*** The meeting begins at 6:00 p.m. ***Public hearings begin at 6:15 p.m.*** This may be the only presentation of this item before the Planning Commission and you are invited to attend.

This conditional use permit application will be introduced for public hearing at the **November 3, 2014** Planning Commission meeting. The Planning Commission members may submit questions to the Planning Commission Clerk concerning the matter or request for more information from the applicant at the time of the introduction. All questions and requests submitted by the Commission shall be in writing and copies will be provided to the applicant and made available to all interested parties and the public upon request. Answers to questions and additional materia requests will be addressed in the staff report for the public hearing.

Commission members may not receive or engage in ex-parte contact with the applicant, other parties interested in the application, or members o the public concerning the application or issues presented in the application.

Application material may be viewed on-line at www.matsugov.us and clicking on 'Public Notices'. Application material may also be reviewed in the Borough Permit Center. If you have any questions or, would like to send us comments, concerning the proposed action, this form may be used for your convenience by filling in the information below and mailing it to the Matanuska-Susitna Borough, Development Services Division Planning Department, 350 East Dahlia, Palmer, Alaska 99645. You may fax comments to 861-7876 or e-mail to *slee@matsugov.us*. For additiona information please contact Susan Lee, Planner II, at 861-7862. Comments received by ***5 p.m., October 31, 2014*** will be included in the Planning Commission packet for the Commissioner's review and information. Please be advised that comments received from the public after that date wil not be included in the staff report to the Planning Commission but will be provided as hand-outs to the Commission. If there is not enough room below, please attach this sheet to another piece of paper. **In order to be eligible to file an appeal from a decision of the Planning Commission, a person must be designated an *interested party*. See MSB 15.39.019 for definition of "*Interested Party*". The procedures governing appeals to the Board of Adjustment and Appeals are contained in MSB 15.39.010-250, which is available on the Borough internet home page (http://www.matsugov.us), in the Borough Clerk's office, or at various libraries within the borough.**

RE: Concerns regarding proposed Monofill

Matanuska - Susitna Borough
Development Services
OCT 20 2014
RECEIVED

SUMMARY: The proposed monofill activity poses a significant threat to public heath from materials blowing off site and to water quality, including drinking water, from toxic chemicals leaching out of the proposed monofill material. These threats have not been adequately considered by the state, and there is a lack of coordination among agencies in responding to concerns.

There is a long history of trouble controlling water on this property. There is an exposed open aquifer, and considerable evidence, including hydrological studies, showing that activities on the gravel pit property affect the lake levels in at least Canoe, Irene, and Bradley lakes and concern that this may also affect area wells. In addition, water flows off this property to the southwest into wetlands in the Palmer Hayflats Refuge. Water from the gravel pit has caused documented flood damage to at least one homeowner across the Glenn Highway. Central Recycling Services has already had trouble controlling water on the property with dumped material contaminating a small pond, leading to citations from the Mat-Su Borough. Photographs continue to document water on the surface of the property where they want to dump. This despite company officials testimony to the contrary about the water.

Central Recycling Services has shown little ability to regulate themselves and little regard to date for the public concerns or government enforcement actions.

REQUESTED ACTIONS:

-- Ask the state Department of Environmental Conservation to reopen the monofill permit process because of inadequate public process.

DEC approved the permit for the monofill without any public input because the public notice was so inadequate that no one knew about it. As a result, potential Impacts to water quality, including drinking water, and other concerns were not adequately considered.

-- Ask the state Department of Environmental Conservation for a coordinated response to this property to protect the aquifer.

There are multiple agencies and even different divisions within DEC and DNR involved. But none seem to think they have jurisdiction for the impacts this property has on lake levels and potentially our drinking wells. This includes DEC's Solid Waste Division, and Surface Groundwater Section. It also includes DNR's Division of Mining, Land & Water's Dam Safety Office, Division of Water Resources, and Alaska Hydrological Survey. Other state agencies could be involved including Fish and Game and State Parks, but it's unclear whether they have been consulted.

-- Ask DNR to do a more thorough hydrological study of this area as was proposed in this year's state budget, and in the meantime consider adding stipulations to the property to protect the exposed open aquifer that feeds the area lakes and possible drinking water wells.

In a Jan. 13, 2010 letter to Mat-Su Borough code compliance division, Granite Construction Manager Trevor Edmondson acknowledged the company had dredged in the aquifer that feeds at least Canoe, Irene and Bradley lakes and possibly our drinking water wells.

-- Ask DNR to review whether existing reclamation regulations for gravel pits under Alaska Statute 27.19 have been enforced.

Granite in 2009 told the Mat-Su Borough they were done mining the property. No reclamation appears to have taken place. The new property owners have said they will not need to do reclamation unless they gravel the property.

Matanuska - Susitna Borough
Development Services
OCT 20 2014
RECEIVED

– Ask state officials to require Central Recycling Services to release the hydrological information they have on the property, including from 20 water monitoring wells then owner Granite Construction monitored dating back to at least 2009.
In a Jan. 13, 2010 letter to the Mat-Su Borough code compliance division, Granite general manager Trevor Edmondson refused to release the data, claiming it could be "misconstrued."

Ask DNR to review their decision to deregulate the dam between the two gravel pit ponds that includes the aquifer the feeds area lakes.
The application was approved in 2012 without considering the impact on the area lakes, and potentially drinking water. Granite Construction in their application did not cite the impact on the surrounding lakes even though they knew about it.

Create a committee to study a long-term solution to protecting the exposed aquifer on this property.
This could include a possible private-public partnership to purchase the property to make it part of the Crevasse Moraine – Kepler Bradley State Park greenbelt area. The City of Palmer could consider using the aquifer as a drinking water supply source, as it is reportedly much less mineralized than their current source.

Re: Public Comment Information on Central Monofill Services

As it states in the Matanuska Susitna Borough Codes

Chapter 17.60: Conditional Uses

17.60.030 – "Permit required:
The following land uses are declared to be potentially damaging to property values and usefulness of adjacent properties, or potentially harmful to the public health, safety and welfare: Junkyards and Refuse Areas"

Property Values – *At the first meeting that was held May 14, 2013 @ Palmer Community Center a question that was asked about the property values. Central Monofill Services (It will be Referred to CMS) responded by saying that the site at the Fair Ground shows no decline in value. But CMS did not take in effect that this site was there prior to the construction of the houses. The areas that will be affected are homeowners who've been living in their homes for 20 to 30 years. – It's a business and I'm aware that its all about the bottom line and so is the investment in my real estate. My suggestion to the board is that CMS do an extensive research to find out how damaging it will be to the surrounding neighborhoods. Why should 2 people have the benefit of improving their lives when it is devaluating others?*

Harmful to the Public Health – *Asbestos, there are 2 ways it can enter the body (this information came from another states Department of Health, no matter where you live, Asbestos is the same). First Inhalation and the second is Ingestion.*

Inhalation - *The concern of it getting air born is always a possibility if they don't follow the proper procedure in transportation. As you know with the winds here in the Valley reaching up to Hurricane Strength. How do we know that they will follow through on their commitment to do the right thing? As I stated at the meeting they already received 3 citations from the Borough and that makes CMS unreliable.*

Ingestion – "The digestive system can be exposed to asbestos from drinking water and mucous cleared from the lungs. A small number of fibers may penetrate the cells that line the digestive system, but only a few will reach the bloodstream. These fibers will be released in the urine."

"The health effects from oral asbestos exposures are unclear. In some areas where residents are exposed to asbestos fibers in **DRINKING WATER**, cancers of the esophagus, stomach, and intestine may be greater concern."

QUESTION - *If CMS is going to be the first to accept Asbestos in the State of Alaska what regulations are in place to protect the residences and do they have the proper training to handle this dangerous item?*

17.60.040 – "Application Procedures:
General. An application to the planning commission for a conditional use or modification of an existing conditional use may be initiated by a property owner or the owner's authorized agent. An application for a conditional use shall be filed with the planning director on a form provided by the planning department."

1) "The application for a conditional use permit shall be accompanied by an a appropriate filing fee as established by the assembly, payable to the borough.

(B) ***Site plan***. A detailed site plan showing the proposed location of all buildings and structures on the site, access points, buffering, drainage, vehicular and pedestrian circulation patterns, parking areas and the specific location of the use or uses to be made of the development shall be submitted with the application."

QUESTION - *How can they submit their plan when the expansion of the Glenn Highway is still being worked out?*

"(C) Action by planning commission.

(1) The planning commission shall hear any interested parties and shall render a decision on the application for a conditional use permit within 30 calendar days from the date of public hearing. In recommending the granting of a conditional use, the planning commission shall state in writing the conditions of approval of the permit, which it finds necessary to carry out the intent of this chapter. These conditions may increase the required lot size, control the location and number of vehicular access points to the property, ***require screening and land filling where necessary to reduce noise and glare, and may require the reclamation of property to a character in keeping with surrounding lands.*** The commission may impose other conditions and safeguards designed to ensure the compatibility of the conditional use with other lawful uses."

QUESTION - *What about the company who sold the property shouldn't they comply with their permit obligations or dose that go away when the property is sold?*

Matanuska - Susitna Borough
Development Services
OCT 20 2014
RECEIVED

"17.60.100 - General Standards:
(A) A conditional use may be approved only if it meets with the requirements of this section in addition to any other standards required by this chapter.

(B) In granting a conditional use permit, the planning commission must make the following findings:

****(1) The conditional use will preserve or not detract from the value, character, and integrity of the surrounding area;***

****(2) That granting the conditional use permit will not be harmful to the public health, safety, convenience, and welfare;***

(3) That sufficient setback, lot area, buffers, or other safeguards are being provided to meet the conditions listed in subsections (B)(1) through (3) of this section; and

(4) The conditional use fulfills all other requirements of this chapter pertaining to the conditional use in this section."

QUESTION – *I want to know who will Guarantee our property and Health Values and Expenses?*

17.60.110 – "Junkyards And Refuse Area Standards:
(A) No junkyard or auto wrecking yard shall be established or operated unless the wrecking yard is completely obscured from the view of any traveled or public right-of-way. The permit may require the junkyard or auto wrecking yard not within a building to be contained within a continuous solid fence no less than eight feet in height, if such requirement is necessary to prevent the unsightly display of the yard or for public safety purposes. Fencing may be of one or a combination of the following:

(1) Conventional solid wood or metal fencing;

(2) Evergreen or other natural planting sufficient to provide year-round screening; and

(3) Earthen berm or topography.

(B) In all cases, fencing provided shall be continuous and of sufficient density to provide visual screening required by this chapter on a year-round basis."

QUESTION – *What about the views from the homeowner's windows?*

They were caught *dumping prior to getting their application, they were told to stop all dumping and to remove all debris from the site and they also received 3 citations for these infractions.*

QUESTION – *Was the buried waste removed or are they just planning on paying the fines? How can we trust them to do what they are supposed to do when they already showed their true intentions?*

Other issues

1) The Pond's that were dug by Granite are still not fixed, they are still causing problems on the adjacent lands, just for example the lake level on Canoe Lake is up to 2 – 3 feet and it was found that one of the ponds in the gravel pit breeched the aquifer. Who will be responsible for fixing this?

2) We need to find a happy middle ground, so far to date these gravel pits have created 3 issues. The prison, coal power plant, and now a dumpsite that will accept Asbestos. Is there any way that we can be proactive and to have a land swap to make this land part of the Matanuska Park system?

3) Create New Codes and Standards to regulations for Refuse / Dump areas to include Recycling, Hazmat and general waste.

Matanuska - Susitna Borough
Development
OCT 20 2014
RECEIVED

Matanuska-Susitna Borough
Planning & Land Use Dept

" The Mat-Su Borough needs a strong and sustainable economy; which is obtainable through common-sense leadership." With that statement it bring up some of the mistakes the Borough has done in the past that has caused excess of amount spending such as the Ferry. Planning is a very import part of the economic growth, by building the Ferry before a deal to secure dockage was putting tax pay's money at risk and now we are paying the consequence.

"Open for Business" is the mayors statement and we all understand the only way to grow is to develop. But in developing we need to attract the "Right Kind of Business" that will employee more than a hand full of people, Public safety and health and business that require Industrial locations to be placed in Industrial zoned areas.

I would like to bring to your attention to the CMS Monofill that is becoming a major issue for a lot of people. It's not to say we don't want businesses to be developing in the Mat-Su or "Palmer" but the Right Kind of Businesses. I sure your well aware of the all the problems that are occurring and the hard ship on the people who choose to live in Palmer.

CMS is not a partner who I would say is on the "WIN WIN" side of things. Just look at the problems they have started, Anchorage Daily News Reports, "Recycler Sues City Over Disposal Discount for $100,000.00" (ADN 03/ 01/14), In Palmer Court they were found guilty in 6 citations for Illegal Dumping. I've been in business and my rule of thumb, is Strong Business Ethics, Trust, and a "Win Win Partnership." No matter what CMS promises and how they think they will take care of problems that arise, their records show it all.

I took the liberty to do some research to show you that this is a bad deal all based on how much the Borough will lose in taxable income. Taxable income is a vital need to keep the Mat-Su Growing but if you start losing it, where will you find it to make it up, by Raising Taxes? I went to the "Mat-Su Borough Parcel Viewer" to first see how many properties are located with in a one-mile area of CMS property boundaries. From my calculation there are 415 +/- private property owners, some with million dollar homes on them.

My process, I took 5 random properties assessments from each subdivision (Canoe Lake, Crimson View and Sky Ranch). I worked out the loss of income that will generate if this Dump goes through. Based on the assessment tax for these 15 properties the loss will be from $270,126.00 to $675,315.00, not good. And not to mention the other loss of income to the Boroughs own land fill; CMS will be dumping tonnage on their on property to avoid paying it fair share.

You have the power to make the right choice to protect the Gateway of Palmer from the smell of Leaking Decomposing Gas (Same Smell at Highland Facility), Unsightly Trash, Contaminating Drinking Water and to the 415 property owners of Palmer who's hard earned investments that are at stake. None of this would have come to a head if the Borough enforced the "Reclamation clause in the gravel pit agreements."

Sincerely,

William Quantick

Mat Su Borough Loss of Income

5 Random Home's in each of the 3 subdivision located with in 1 mile * of the purposed CMS Dump disposable area.

Total	$1,373,600.00	$82,416.00	$137,360.00	$206,040.00

All Total	$4,502,100.00			
Loss of taxable Assessment		$270,126.00	$450,210.00	$675,315.00

Note: All figures are from the 2013 Mat-Su Borough Tax Records

There are 415 plus property owners in the 1 mile area. if you take all of these figures and add them together there will be a greater loss of income to the Mat-Su Borough. in addition they are also planning on disposing Asbestos a Hazardous material, which increases the area to two miles out. It will effect more property with additional loss of revenue and at a higher rate.

The Boroughs loss of revenue is one thing but it is far more devastating to the property Owner who will lose 6% to 15% right off the real estate value of their properties.

Additional loss of revenue to the Mat-Su Borough is from its own Land Fill

* State of Alaska Residential Real Property Transfer Disclosure Statement, Pg 5 line 23
** MSN Real Estate Study by AZ Assessor's Office
*** University of CA states if Hazardous waste (Asbestos) is dumped.

Matanuska - Susitna Borough
Development Services
OCT 20 2014
RECEIVED

FIRST CLASS MAIL

The Matanuska-Susitna Borough Planning Commission will consider the following:

Application or Item: *Application for a conditional use permit for the operation of a monofill for the disposal of inert material*

Matanuska-Susitna Borough Code Section: MSB 17.60 – Conditional Uses

Applicant: Central Monofill Services 15#3001 B040

Request: *An application has been submitted for the operation of a monofill for the disposal of inert material. The inert debris will primarily be non-hazardous shredded residual, non-recyclable waste material from construction and demolition waste. Regulation Asbestos Containing Material (RACM) and Non-RACM will also be accepted at the monofill site.*

Location: MSB Tax Parcel# 17N02E18C010 (2840 S. Glenn Hwy.) and 17N02E19B006 (2560 S. Glenn Hwy.); within Township 17 North, Range 2 East, Sections 18 & 19, Seward Meridian.

The Planning Commission will conduct a public hearing in the Borough Assembly Chambers, Palmer, Alaska, on this item on ***December 1, 2014*** The meeting begins at 6:00 p.m. ***Public hearings begin at 6:15 p.m.*** This may be the only presentation of this item before the Planning Commission and you are invited to attend.

This conditional use permit application will be introduced for public hearing at the **November 3, 2014** Planning Commission meeting. The Planning Commission members may submit questions to the Planning Commission Clerk concerning the matter or request for more information from the applicant at the time of the introduction. All questions and requests submitted by the Commission shall be in writing and copies will be provided to the applicant and made available to all interested parties and the public upon request. Answers to questions and additional materia requests will be addressed in the staff report for the public hearing.

Commission members may not receive or engage in ex-parte contact with the applicant, other parties interested in the application, or members o the public concerning the application or issues presented in the application.

Application material may be viewed on-line at www.matsugov.us and clicking on 'Public Notices'. Application material may also be reviewed in the Borough Permit Center. If you have any questions or, would like to send us comments, concerning the proposed action, this form may be used for your convenience by filling in the information below and mailing it to the Matanuska-Susitna Borough, Development Services Division Planning Department, 350 East Dahlia, Palmer, Alaska 99645. You may fax comments to 861-7876 or e-mail to *slee@matsugov.us*. For additiona information please contact Susan Lee, Planner II, at 861-7862. Comments received by ***5 p.m., October 31, 2014*** will be included in the Planning Commission packet for the Commissioner's review and information. Please be advised that comments received from the public after that date wil not be included in the staff report to the Planning Commission but will be provided as hand-outs to the Commission. If there is not enough room below, please attach this sheet to another piece of paper. **In order to be eligible to file an appeal from a decision of the Planning Commission, a person must be designated an *interested party*. See MSB 15.39.010 for definition of "*Interested Party*". The procedures governing appeals to the Board of Adjustment and Appeals are contained in MSB 15.39.010-250, which is available on the Borough internet home page (http://www.matsugov.us), in the Borough Clerk's office, or at various libraries within the borough.**

Location/Legal Description of your property: CANOE LK BLK 1 Lot 2

Comments:

Note: Vicinity Map Located on Reverse Side

Hi my name is Bill Quantick and I'm here to voice my concerns about this permit application and will like to state that the idea of recycling is a good plan and also would like to bring to your attention to the Mat Su Borough Codes Under the heading of Conditional Use Chapter 17.60.030

Potentially Damaging to Property Values and Potentially Harmful to public Health, Safety and Welfare: "Junkyards and Refuse Areas."

First I would like to address **Damaging Property Values –**

Central Monofill Services (CMS) - States that **Property Values** will not devalue?

How do they know this?

What kind of research was assigned to this?

Is this part of the application process?

And who will be responsible for my Investment loss if this permit gets approved?

Second

Does asbestos exposure cause health problems?

Breathing it we already know it causes LUNG CANCER and

ME-SO-PTHELIOMA

But there is "The health effects from oral asbestos exposures which are **presently unclear**. But in some areas where residents are exposed to asbestos fibers in DRINKING WATER, cancers of the esophagus, stomach, and intestine may be of greater concern." Something to keep in mind.

Matanuska - Susitna Borough
Development Services
OCT 20 2014
RECEIVED

Other issues that I'm unclear of are the **Transportation** - As for the regulated Asbestos are they going to transport according to U.S. EPA Standards?

Matanuska - Susitna Borough
Development Services
OCT 20 2014
RECEIVED

The Next Code

17.60.100 - General Standards:

(A) A conditional use may be approved only if it meets with the requirements of this section in addition to any other standards required by this chapter.

(B) In granting a conditional use permit, the planning commission must make the following findings:

***(1) The conditional use will preserve or not detract from the value, character, and integrity of the surrounding area;

***(2) That granting the conditional use permit will not be harmful to the public health, safety, convenience, and welfare;

(3) That a sufficient setback, lot area, buffers, or other safeguards are being provided to meet the conditions listed in subsections (B)(1) through (3) of this section; and

(4) The conditional use fulfills all other requirements of this chapter pertaining to the conditional use in this section.

In the mean time they are in the process of applying for their application but were caught dumping, and were told to stop all dumping and to remove all debris from the site.

They also received 3 citations for these infractions.

Matanuska - Susitna Borough
Development Services
OCT 20 2014
RECEIVED

My QUESTION to the Borough

Was the waste removed? If not...
What are you going to do about it?
Or are you just going let them pay the fines and reward them with a permit?

The Meaning of
Integrity – Adherence to code of values
Trust – The truth of someone

How can we trust them and believe in their integrity when they already showed their true intentions?

There are other questions
120 acres track they say they will only use 48 acres, what will become of the remain 72 Acers?

They said only 3 to 4 trucks per day but the permit states up to 100 trucks per day?

And who will responsible to repair the rising water in the surrounding lakes?

What to do? Suggestion

Stick to the 2007 Matanuska-Susitna Borough Core Area Comprehensive Plan, which makes this area Educational/Medical/Glenn Parks District

Or

Market it as a residential area Easy 40 min commute to Anchorage, Lake front property, mountain, and Glacier Views.

Thank you,

Topic – Central Monofill Services

Not sure if you are aware that Central Monofill Services has purchases land from Granite and it is just south of Palmers city limits

Central Monofill Services is in the process of trying to develop a landfill for non-recyclable building material.

This location will be accepting ground up material from construction demolition, which will consist of Sheet Rock, Roof Shingles, Paint, Metal, Pressure Treated Lumber, and Asbestos, just to name a few items. This material is coming from Anchorage and other areas because this location is prime for their needs.

There are issues that need to be address such as

- A Breached Open Aquifer less than 300 yards from the fill site
- Local Community and private Wells
- Rising Lake Levels
- And The Appearance to the Gate Way To Palmer

And the 2 most important issues Health and Property Values

Lets say if the City Of Palmer ever Annex this area they will be having to deal with this Problem, I do hope that you have some influence to see that this greedy project is short lived.

OCT 20 2014
RECEIVED

Matanuska Susitna Borough
Planning & Land Use Dept.

I am a resident of the Mat- Su and reside just south of Palmer's city limits by the Grante Gravel Pits. The reason for this letter the gravel pit on the left side as you head north has been sold to Central Monofill Services and they are seeking permission to be come the first State Wide Asbestos dump site. Their plan is to recycle as much of the products they can but in the process there is always the worst of the worst left over.

This group finds this location to be ideal or I should say logistically centrally located. In return they would cut cost on getting this dangerous waste to this location to be profitable.

The concept is good for Alaska but not good for the surrounding area. What I mean is that when I first moved to area I found my house and I accepted that there was a gravel pit next door not a dumping ground for this "New Business" other wise I would have found another location, listed below are a few bullet points.

- Property values
- Hazardous material
- Health

I do have a few suggestions

Borough Land Swap - That will place this in a location that makes cense
To be proactive - Make this gravel pit part of the park system so we don't have to go through this again (Prison, Power Plant) or zone it residential

I'm not sure if you have any control to help but I'm asking.

Sincerely

Bill Quantick

To: Susan Lee
Subject: Please OPPOSE the CENTRAL MONOFILL SERVICES Permit

Ms. Lee,

I urge you to consider our environment, our livelihoods, and the families in our community and keep potentially hazardous disposal sites AWAY from our housing, farming, water wells and recreational areas. I chose to move back to Palmer to raise my family in a rich, unspoiled rural community. I purchased my home off Cienna Drive 4 years ago and am strongly opposed to the idea of allowing any kind of land fill to occupy the gravel area located at the proposed site. Please consider that this proposed site is in the heart of our community, surrounded by lakes, recreational areas, farms, family homes and very near the State Fair Grounds. I can't imagine a worse location for a waste disposal site. Please protect and safe guard our community from what will absolutely cause damage to the environment, air quality, ground water and overall quality of life to nearby residents and borough residents alike. The CMS Permit threatens the very quality of life that brought us back to the borough.

http://ewssite.com/how-it-works

Sincerely,
Linnzi Doerr
907-360-8394

How our landfill works

Our landfill is among the most technologically advanced in the United States. Here's why:

Choosing the site

Environmental Waste Solutions specializes in reclaiming former mine pits, and turning them into carefully designed landfills that are classified for "beneficial use" according to approved Civil Engineering applications. We study the proposed site to determine:

- The area of land necessary for the landfill
- The composition of the underlying soil and bedrock
- The flow of surface water over the site
- The impact of the proposed landfill on the local environment and wildlife
- The historical or archaeological value of the proposed site

EWS works to take otherwise unusable land and make it productive during the short term. Our long-term goals include turning the land into wooded preserves.

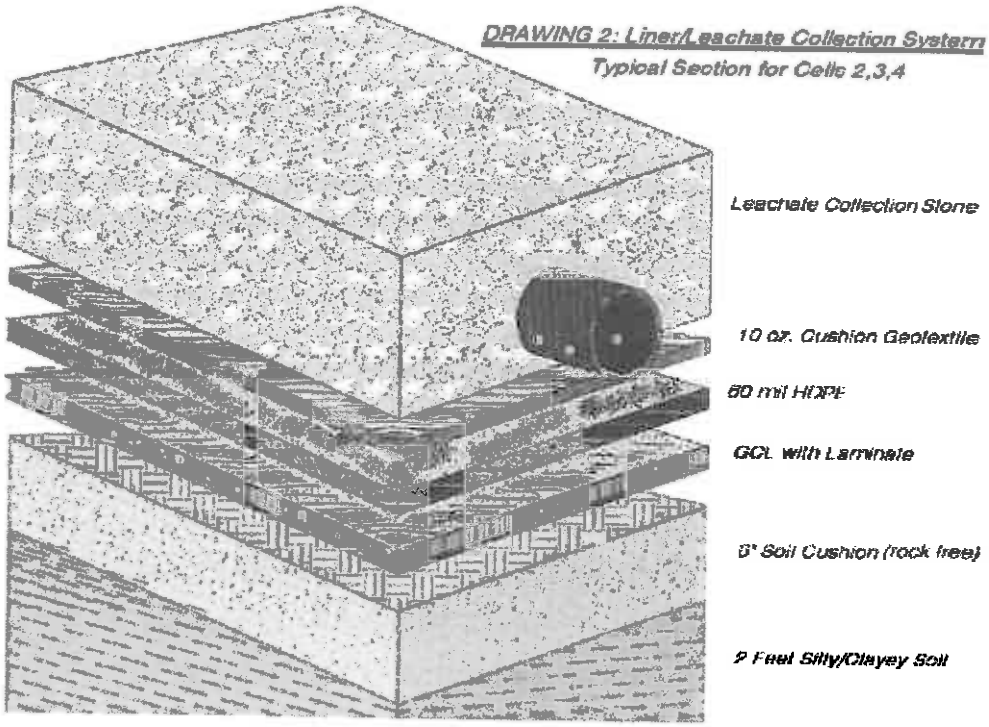
Building the landfill

Our sites are thoughtfully designed and highly engineered to exceed state requirements and are professionally run to keep the community safe.

The basic parts of a landfill are:

- **Bottom liner system** – separates landfill content and subsequent leachate from groundwater. Leachate is liquid that drains downward through the landfill.
- **Individual cells** – where the material is stored within the landfill
- **Storm water drainage system** – collects rainwater that falls on undeveloped portions of the landfill and runs off without contacting waste material.
- **Leachate collection system** – collects rainwater that comes in contact with waste material and collects the water for treatment and proper disposal.
- **Covering or cap** – seals off the top of the landfill

Each of these parts is designed to address specific challenges that are encountered in a landfill. So, with each part of the landfill, there is a problem to be solved.



Bottom liner system

A landfill's major purpose and one of its biggest challenges is to contain the waste so that potential problems are contained. The bottom liner prevents the waste from coming in contact with the outside soil, particularly the groundwater. EWS uses a 6-foot liner between the ground clay and man-made materials being deposited. The liner is triple lined on the sides and quadruple-lined at the base, far exceeding requirements.

Mono-cell construction

Landfill content is compacted into areas, called cells. The material within the cell is compressed by heavy equipment (tractors, bulldozers, rollers and graders) that go over the day's accumulation several times. It is covered with six inches of soil and compacted further. Lifts are arranged in rows and layers of adjoining cells.
EWS stores a specific type of waste throughout the landfill, hence it is a "monofill" composed of "monocells. This means that 10 or 20 years in the future, if and when it becomes economically feasible, the landfill can be mined and its contents harvested for use.

Storm water drainage

Our sites are built to minimize water discharge. This is done in two ways:

- **Prevent rainwater from entering site.**
  We cover the cells daily to keep out rainwater.
- **Drain water away.**
  To exclude rainwater, the landfill has a storm drainage system. Plastic drainage pipes and storm liners collect water from the landfill and channel it to drainage ditches surrounding the landfill's base. The ditches carry water from collection areas to the side of the landfill.

Leachate collection system

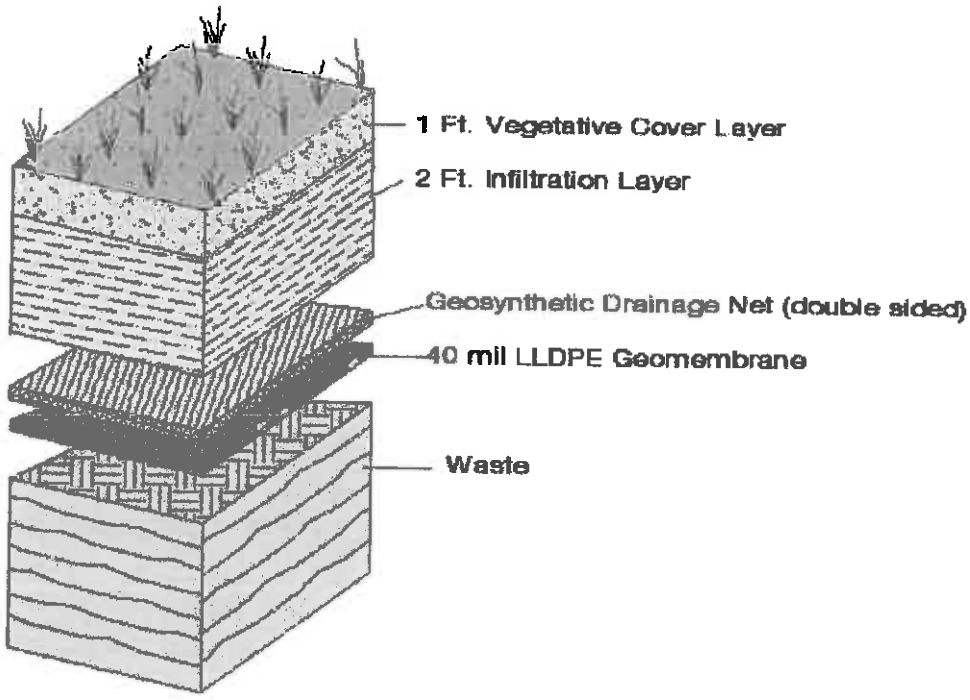
There is no perfect system to exclude water from a landfill. This water runoff called, leachate is typically acidic. To collect leachate, perforated pipes run throughout the landfill. These pipes then drain into a leachate pipe, which carries leachate to a leachate collection tank. The leachate is tested and allowed to settle. After settling, all water is professionally treated.

Groundwater monitoring

At many points around the landfill are groundwater-monitoring stations. These are pipes that are sunk into the groundwater so water can be sampled and tested for the presence of leachate chemicals. EWS uses three times the number of test wells required, just feet away from the waste stream. More test wells allow us to detect potential situations before they can become a problem.

Covering or cap

DRAWING 2: PROPOSED FINAL COVER SYSTEM



Waste deposited in the landfill is covered each day with six inches of a clay and gravel mixture called chert. This covering seals the compacted waste from the air and prevents water from getting through. When a section of the landfill is finished, it is covered permanently with a polyethylene cap (40 mil). The cap is then covered with a 2-foot layer of compacted soil. The soil is then planted with vegetation to prevent erosion of the soil by rainfall and wind.

Responsible landfill operation

EWS accepts shipments only by contractual agreement from industrial partners who need to dispose of byproduct in an environmentally responsible way. During landfill operations, incoming trucks are weighed on arrival and their load is inspected. Next, the vehicles unload at the tipping point. A warehouse is located on-site, so that if it's raining, covered trucks can come into a closed building and safely offload. This means we can receive shipments 365 days a year, rain or shine. After loads are deposited, bulldozers are used to spread and compact the new material on the working area of the landfill. At the end of the day, the working cell is covered with chert and compressed until it becomes impermeable.

Recycling Ventures

Recycling Ventures is a new endeavor created in alliance with EWS to develop economically feasible methods to reduce, and eventually eliminate, salt cake waste. Recycling Ventures takes the waste stream being landfilled by EWS and recycles the waste in alignment with current best practices. We are hopeful to be able to reduce the amount of waste by 1-15% through our recycling process.

Recycling Ventures is an environmentally sensitive company that uses no chemicals to separate the aluminum from the salt cake. Additionally, Recycling Ventures has considered the environment first through the design and construction of our facility and stands ready to implement additional technology that shows further waste reduction in the future.

With this said, Recycling Ventures is pursuing future design and implementation of technology that will eventually provide the ability to fully recycle the contents of salt cake. By joining forces with EWS, Recycling Ventures hopes to be a valuable asset to the Camden community as it pursues and implements this technology.

What happens long term?

When a landfill closes, EWS will continue to monitor the site and groundwater. Upon complete maturity, it will be capped and a forest will be planted over it, resulting in a densely wooded mound where once there was a landfill.

Subject: Stop Private Dumps comment

Re: The private dump slated for the location of the Glenn Hwy. at mile 38.3.

It is my opinion that there should never be a dump site placed anywhere the vicinity of any bodies of water nor anywhere near residential neighborhoods. Also, there should always be strict regulations and oversight to be sure these regulations are adhered to when it comes to disposing waste that materials that are dangerous contaminants. I don't think people really understand the dangers of contaminants entering into our aquifers and what it can do. There were two national cities with water crises just this year where the water became contaminated. We can't live without clean water.
Why would the Alaska DEC even think of tentatively approving something like this when they are so strict on everything else. We hope the borough takes this issue with great review and thought.

A concerned Mat Su Valley homeowner

Subject: Central Environmental INC

As a resident of the State Of Alaska since 1973 and a property owner in the MSB since 1993 I'm submitting my positive comment concerning the Conditional use Permit applied for by Central Environmental INC.
It is my opinion that the MSB needs sites for disposal such as this to insure that materials left over from demolition be disposed of in the best possible way to protect the environment. There are many examples of improperly disposed of materials throughout the MSB. The central location of this site near the greatest population density is ideal. I'm confident that since CEI is all ready in the business of disposal they will abide by the MSB rules for safe disposal.
In addition Mr. Shane Durand has demonstrated his interest in supporting community events by allowing the Alaska Model Boat Club to use his lake on said property for the running of radio control boats. The Club is a member of NAMBA which is a national organization which oversees the safe operation of these models.

Thanks you for this opportunity to make my comments heard.
Sincerely
Timothy R Johnson

Subject: Monofill

Hi Susan and Planning Department,

I wanted to comment on the proposed mono fill at 2849 S. Glenn Hwy near Palmer. My family and I live near the proposed site and are extremely opposed to this measure. I hear a lot of anger around the neighborhood as well. My concerns stem from both the potential for air and groundwater contamination. I have two young sons, one of which has breathing problems. The wind blows extremely hard out in this area and I want assurances that debris (especially asbestos containing particles) will not blow off the site and straight into my neighborhood. This goes without mentioning potential groundwater contamination in our nearby wells and the smell that may even reach the fairgrounds that can put a damper on the events held there. We don't want a site like this that can risk the health of our family, decline our property value, and just become a general eyesore to the palmer area.

A VERY strong NO from us!

Sincerely,

Dustin and Angela Boller

Subject: Proposed Palmer Monofill dump site

I can only think of two reasons this proposed material dump is being considered again by MY local government: mismanagement of bureaucratic processes before, during, or after the original denial was issued, or making the decision based on greed over the protection of our city's health and resources. Neither option reflects well on the members who allowed this to happen.

The location of the site should be of principal concern. It is nestled in among lakes and streams in a beautiful area where many of us grew up exploring and fishing as children. More importantly, these lakes and streams are direct lines of contamination into a giant aquifer which the areas residents draw drinking water from. ANY potential for contamination is an unacceptable risk, and given the materials which are to be dumped there, already poses an unacceptable level of risk and shows a complete disregard to the health and well being of the citizens of Palmer. It would be a negligent act for a governmental entity to permit such actions occurring, and exposing their constituents to such a risk.

The Munter Report has already concluded that well contamination is probable. With a slogan coined by Shane Durand stating, "The solution to pollution is dilution" shows the mentality of this company. Under NO circumstances should we permit a company like this to operate a facility that has direct impact on our health. This company has a recorded history of scoffing at regulatory practices. Do not give them another chance.

We have, as a city, achieved steady growth and healthy home market rates in the face of much economic turmoil. To consider permitting a company to do this will pour all of this down the drain. Why would we allow it in a prime location which could either be allocated for either housing development, trail systems, or wilderness area (only 3 of many options) which would BOOST the value of land and homes in the city instead of deterring investment in housing and local economy, while decreasing land and home values (and the associated tax income the city makes)?

If this dump is allowed, I will be sadly be leaving my hometown with my family in tow for fear of their health. It's a shame to think that our representation may allow the destruction of my beautiful corner of the earth through "legalized" and permitted ecological pollution.

I can guarantee that at the first sign of pollution or contamination, something similar to the Clean Water Initiative will be brought forth on to the City of Palmer, along side the Clean Waters Act of 1972 (33 USC 1251) where to EPA will investigate the permitting process. How can I make this guarantee? Contamination and misrepresentation reports to the Federal Government are free, easy, and require that they follow up. And there will be a lot of angry Alaskans who like to get involved.

All of this begs the question: why even allow it in the first place? It only does a disservice to the city and it's residents, as well as place an even heavier burden on the local government to authorize such permitting in the future when a responsible company applies. Stop the process before it begins.

Subject: Toxic Dump

We can live without gravel but we can't live without good water.
We can find other places to dump waste but we can't find other water sources once it is contaminated we can't get it back.
Please do not permit this dumping in the area of all those lakes or streams along the Glenn Hiway from Palmer to the river bridges or anywhere from the Landfill now in operation by the borough to the Matanuska River by CMS or any other organization/company and etc. that would create a dump of any kind .
Thank you
Katie Rousey

Importance: Low

Please read attachment statement above. STOP THIS PRIVATE DUMP at mile 38.3 .

11/6/14

I, Daniel Delaney, am an Electrical Administrator, Master Electrician and contractor, business owner and home owner in this area. I am strongly against a dump in this area, because this is all wet land with birds, fish, bears, and all forms of Alaska wild life.

The wet land is critically important to all the families with wells in the area. This would poison the water and pollute the lands for families, pets, fish, large birds and other wild life. We all have been here longer than these most self-serving lands rapists. They have already been witnessed dumping in this location after hours of operation by several local land-owners. Who knows what kind of damage this has already done?

A home development or subdivisions in this area would be a much more productive use of the land and lakes on this proposed property. This would give families homes; some of which could be gorgeous lake front and lake-ridge homes with beautiful surroundings. This could create a wonderful community, work for hundreds of workers and businesses, and income for the community and surrounding towns well into the future. However, a dump in this area would destroy the land forever.

The dump would poison the water for the community and all surrounding wildlife. What this area needs is not a dump, polluting the land and water for all, but to sustain its clean, non-toxic, glacier water. This land needs to remain garbage free.

This is one of the most scenic areas in our Mat Sue Valley. Its will be seen from everyone traveling in and out of our beautiful state of Alaska, U.S. Highway #1, a port hole in and out of our states largest cities as well as all the fair goers and tourists visiting from all over the world. Even to propose such a sight in such a beautiful area shows the lack of concern for our lovely surrounding's and pristine water ways.

What this will do to this area is worse than the pebble mine and that Alaska voted not to allow.

I ask please for the benefits of all do not allow this toxic waste land in this location.

Sincerely concerned local resident and business owner Daniel R. Delaney.

Subject: Monofill MISTAKE comments

To whom it may concern, the CMS Monofill has been and is still a terrible mistake, if built at the presently proposed site. After countless hours of research and efforts in understanding the irreversible damage that will take place if this monofill is built in this hydrologically sensitive area that hydrates the local area and that is also positioned in the dead center of two valleys that produce consistently high winds that will continue to spread trash and particulates across adjacent land and into the air, it is CLEAR, IT IS STILL THE WRONG SITE.
Property values will be negatively affected also.
These issues that are but a few of many that lay the foundation for the NO, when asked, should this monofill go forward at the present location?
The public and community are relying on good judgement that is expected of the appointed commission to refuse this CUP APPLICATION. This monofill will benefit a handful financially, while affecting a large amount of hard working, tax paying, property owning FAMILIES in the direct vicinity, adjacent and opposite the proposed site, along with all residents of Palmer.
The water ways and lakes located from within a 1000 feet and a few miles will be adversely affected, these lakes and creeks are stocked by the state and also have naturally running trout and salmon.
The scenic byway that runs past this atrocity, past the STATE FAIR GROUNDS then into Palmer is supposed to be protected by local and state government.
If this application is approved it will show that the local appointed commission has demonstrated gross misconduct and neglect and direct disrespect for the community.
With all of the pushback and viable evidence and argument from the community, if this CUP is granted it will fortify the foundation for legal action by the community.
PLEASE PLEASE PLEASE do not allow this monofill at THIS SITE. FORCE CMS to FIND ANOTHER LOCATION.
CMS PLEASE DONATE THIS LAND TO GREAT LAND TRUST, so as it may be PROTECTED,and put to GOOD USE FOR OUR COMMUNITY.
Ultimately the COMMUNITY will PAY for a CMS MISTAKE.
CMS, show that you are a good entity and do the right thing, everybody knows what that is.

With Respect, Sincerity, and Good Judgement, Zennon McNeill

Response for Comments

Project: Application for a conditional use permit for the operation of a monofil

Parcel ID: Township 17 North, Range 2 East, Sections 18 & 19, Seward Meridian

Applicant: Central Monofill Services

As a resident of Palmer, a lifelong Alaskan, a homeowner, and a mother I wish to voice my concern and oppose the permit of a monofill at location: Township 17 North, Range 2 East, Sections 18 & 19, Seward Meridian. My water source is fed by the aquifer under this proposed site, which has already been documented to have been punctured by the previous owners. In NO way is this a justified or acceptable calculated risk of potential contamination of the water that my family drinks everyday and feeds my gardens in the summer to only then be consumed by us. We must protect our water source today and for the future of our children. I believe that there is no need to have a monofill dump anywhere within a residential location. There is beautiful water recreation area that sits right next door that must be protected also for future generations. Once the damage is done it is nearly impossible to correct so the only thing we can do is not allow the potential contamination to occur to begin with. Please consider a denial in this permit process and demand that Central Monofill Services finds an acceptable location to conduct this monofill elsewhere.

Subject: Palmer toxic dumping

We have lived in Palmer for over six years and love the area we live in. The town, farmland, lakes and hiking trails near us are what drew us in to this area near the fairgrounds. We are saddened and disgusted by the thought of a private dump being allowed to open not far from our home. Not only will this be an eyesore on the way to our quaint town of Palmer, but the environmental impact it will have on the land, the air, and in our drinking water is what concerns us the most. If this dump is approved, this will greatly impact the decision for our family to stay and live in Palmer. We didn't move to Palmer for access to dumps. We moved to Palmer to raise our family in an area that we love, filled with beautiful views, hiking trails, lakes, farmland, and the small-town feeling. This dump has no need to be put right in the middle of all of that and risking the health of the people who live here and the land we live on. Please do not allow this to go through. We greatly oppose this dump.

Subject: Proposed Dump in Palmer

There are several reasons that the proposed site for the monofill dump on Glenn Highway in Palmer is unacceptable:

1. The risk of contamination of the local ground water is too great. The drinking water is among the best anywhere, and it would be a tragedy to contaminate such an important natural resource.

2. This area experiences high winds which will undoubtedly spread the garbage throughout a large area of the Valley. I haven't seen appropriate safeguards proposed to prevent this.

3. There are no reliable plans to ensure that only certain, and safe, materials are brought into the dump site. Self-policing will not work. The proposing company has already proven itself to be untrustworthy because it has lied and disregarded safeguards and regulations.

4. Plans to beautify the area, and make the land usable and productive have not been published. What a site this mess will be! Unacceptable trashing of our beautiful landscape will have a detremental effect on our qualify of life, our health, our recreation options, the local wildlife, the economics of home values, and the desireability of the location for housing and business development.

The permit application for the proposed dump site must NOT be approved, at this time, or anytime in the future.

Sincerely,

Susan Franznick

Subject: Thoughts on Central Monofill Services permit application

Dear Mat-Su Borough Assembly Members,

We live in Sky Ranch Subdivision off of Outer Springer Loop. We have several concerns about Central Monofill Services' request for a Conditional Use Permit to open a monofill just off the Glenn Highway near Palmer.

Our first concern is our water supply. It is known that the aquifer was breached by the gravel pit company, this means that if there is contaminated runoff from the monofill, our water supply is in danger. We have read of a monofill sites in Ohio that have toxins leaking. Right now we are enjoying pure clean water, the best drinking water that we have ever had and we have lived in several different areas of the United States. What will this do to our water in a few years? No one knows. That is a problem. Where will the area residents get their water if the aquifer is contaminated? Water is essential for life.

Traffic is another concern. We already have gravel trucks turning in that area. We have to deal with the train blocking Outer Springer Loop and Inner Springer. Now add more trucks turning in the same area and we are going to have traffic problems. The fair is only ten days, but the traffic on the Glenn in that area is very congested during that time. We don't even attempt to make a left hand turn onto the Glenn during the State Fair; we go around on Outer Springer Loop, through town, to the Palmer Wasilla Highway to Trunk to the Parks if we need to go to Anchorage or Wasilla.

Windblown debris is another concern. Anyone who lives in the Palmer area knows that the winds blow and blow hard here. Those who live downwind from the monofill are going to have problems with blowing debris. We have already witnessed this when Central Monofill Services started dumping before they applied for the permit last time. This also brings up the eyesore this is going to be to tourists that come to Palmer. They are going to be driving right by this site.

The monofill is probably needed, but not in a populated area. This is the biggest state in the Union with many acres of land that are not so near residential homes, yet still accessible. Yes, it will cost the company more to transport the materials, but the cost to the residents of the areas will be greater. Having been in real estate in the past, we know that this has the potential to lower home values in the area. It just doesn't seem right to allow a new company to save money while hurting the residents who have been there for many years.

Who is going to take on the resp .sibility of monitoring the monof..l and Central Monofill Services? A private company on Central Monofill Services' payroll, the Mat-Su Borough, or the State of Alaska? Who is going to pay to have water lines installed, when our private wells are contaminated? Who is going to be responsible to clean up the debris from Central Monofill Services?

Please hear the voices of the residents around the proposed site of this monofill and deny the permit for Central Monofill Services.

Thank you for your time and consideration,

Chuck and Vicky Ramage

Construction and Demolition (C&D) Landfills: Emerging Public and Occupational Health Issues

Editor's note: As part of our continuing effort to highlight innovative approaches to improving the health and environment of communities, the Journal is featuring a bimonthly column from the U.S. Agency for Toxic Substances and Disease Registry (ATSDR). The ATSDR, based in Atlanta, Georgia, is a federal public health agency of the U.S. Department of Health and Human Services. ATSDR serves the public by using the best science, taking responsive public health actions, and providing trusted health information to prevent harmful exposures and diseases related to toxic substances.

The purpose of this column is to inform readers of ATSDR's activities and initiatives to better understand the relationship between exposure to hazardous substances in the environment and its impact on human health and how to protect public health. We believe that the column will provide a valuable resource to our readership by helping to make known the considerable resources and expertise that ATSDR has available to assist communities, states, and others to assure good environmental health practice for all served.

The authors of this month's installment, Michelle Colledge and Lynn Wilder are with ATSDR's Division of Regional Operations and Division of Health Studies, respectively. Dr. Colledge is a senior research officer, and earned her MPH from Florida A&M University and her Ph.D. from the University of Illinois at Chicago School of Public Health. She is a lieutenant commander in the United States Public Health Service, and has worked for ATSDR since 1999. Since working in the region 5 office, Michelle has lead multi-agency and multi-disciplinary teams in public health investigations, risk and exposure assessment, and provides technical assistance to partner agencies for emergency response activities. Lynn Wilder is a senior environmental scientist and received her M.S. in industrial hygiene from the University of Pittsburgh. She is a certified Industrial Hygienist and is a Ph.D. candidate at the University of Washington's Department of Environmental and Occupational Health. Since joining ATSDR in 1989, she has worked in areas of emergency response, health and exposure investigations, and health studies.

Historically, construction and demolition (C&D) debris landfills have been considered nonhazardous operations, containing relatively inert wastes such as concrete, asphalt, wood, metals, gypsum drywall, and roofing materials. In recent years, however, it has become increasingly clear that emissions resulting from the decomposition of gypsum drywall and organic debris are a public health issue. Drywall, comprised of gypsum ($CaSO_4 \cdot 2H_2O$), breaks down into hydrogen sulfide and other sulfur compounds under anaerobic conditions and in the presence of water. When exposed to water, the sulfate in the gypsum is dissolved in landfill leachate (Townsend, 1998). Under the same environmental conditions, organic debris degradation produces other flammable gases such as methane. As a result, surface and subsurface fires may occur at C&D landfills (Federal Emergency Management Agency [FEMA], 2002).

Drywall can be a significant constituent of C&D wastes. Depending on the type of construction, it comprises between 5% and 25% of total C&D volume generated (Townsend et al., 2000; United States Environmental Protection Agency [U.S. EPA], 1998). In the United States, C&D waste comprises a considerable portion of the overall solid waste stream. The U.S. Environmental Protection Agency (U.S. EPA) estimated that over 136 million metric tons of building-related wastes were generated in 1996 (U.S. EPA, 1998). Approximately 35%–40% of these wastes were landfilled in C&D facilities. As a comparison, this amount of C&D waste was only slightly less than the 190 million metric tons of total municipal solid waste (MSW) generated that same year (Clark, Jambeck, & Townsend, 2006). In 1996, approximately 1,900 C&D landfills were operating in the United States (U.S. EPA, 1998). At these sites, gas emissions to ambient air are influenced by a number of factors, including, but not limited to, the volume and composition of the waste (particularly gypsum drywall content); engineering design and controls; the condition, composition, and thickness

of the landfill cap; and leachate collection, removal, and handling practices.

Because U.S. EPA does not specifically regulate the operations of C&D landfills, C&D regulation is the responsibility of individual states. Clark and co-authors (2006) recently reviewed and summarized state C&D landfill regulations across the country. The authors found little consistency from state to state in the siting and engineering design requirements of these facilities, in regulatory oversight and rules, or even in a state's definition of what constitutes C&D waste. The authors did find, however, that state standards are generally far less stringent for C&D facilities than for MSW facilities (Clark, Jambeck, & Townsend, 2006).

The Agency for Toxic Substances and Disease Registry (ATSDR) and its federal, state, and local health and environmental agency partners have recently investigated a number of C&D landfills with gas emissions that caused significant community health concerns. Community exposures vary, but are generally greatest during stable meteorological conditions and are generally diurnal with the highest concentrations in ambient air in late evening and early morning hours. At some of these sites, concentrations of hydrogen sulfide gas in residential ambient air were at or above levels known to cause adverse human health effects. At an Ohio C&D landfill, hydrogen sulfide concentrations in residential ambient air approached the National Institute of Occupational Safety and Health (NIOSH) recommended exposure limit (REL) for the occupational ceiling value of 10 parts per million (ppm) (ATSDR, 2003). Improper leachate management at the same site also resulted in community hydrogen sulfide concentrations of up to 95 ppm on at least one occasion (ATSDR, 2006). This concentration is just below the NIOSH immediately dangerous to life and health (IDLH) level of 100 ppm over 15 minutes.

Under normal conditions, hydrogen sulfide is a colorless, flammable gas. It has an odor threshold as low as 0.5 parts per billion (ppb) (ATSDR, 2006), and is typically characterized as smelling like rotten eggs or sewage. When inhaled, hydrogen sulfide readily enters the blood stream via diffusion through pulmonary alveoli. The majority of hydrogen sulfide is metabolized through oxidation into thiosulfate, then further oxidized to sulfate, which is rapidly excreted in the urine. People with preexisting respiratory conditions or immature respiratory systems are more likely to experience adverse health effects from hydrogen sulfide exposure. Those with cardiac or nervous system disorders may also be more likely to experience adverse outcomes from hydrogen sulfide exposure. Although the exacerbation of preexisting respiratory conditions (e.g., asthma) and neurological effects (e.g., headache, nausea, and fatigue) have been noted at low levels (between 10 and 100 ppb), to date, quantifiable irritant effects levels have only been reported with exposures in the low ppm range (Bhambini, Burnham, Snydmillar, MacLean, & Lovlin, 1996a, 1996b; Campagna et al., 2004; Jappinen, Vilkka, Marttila, & Haahtela, 1990; Kilburn & Warshaw, 1995; Kilburn, 1997; Kilburn, 1999). With acute exposures at concentrations at or above 100 ppm, serious injury and death are possible (Hirsch & Zavala, 1999; Milby & Baselt, 1999; Parra, Monso, Gallego, & Morera, 1991; Reiffenstein, Hulbert, & Roth, 1992; Snyder, Safir, Summerville, & Middleburg, 1995; Tvedt, Edland, Skyberg, & Forberg, 1991; U.S. EPA, 2003).

Although ATSDR is not an occupational health agency, staff members have noted worker health and safety issues at numerous C&D landfills. Generally, these facilities have no employee training programs on the use of personal protective equipment and no onsite monitoring programs for common C&D gases. In one case, several employees either lost consciousness or became nauseated and evacuated the work area (Florida Department of Health [FDOH], 2007). In November 2007, four employees died as a result of exposure to high concentrations of hydrogen sulfide while attempting to repair a leachate pump at a C&D landfill in Superior, Wisconsin (Emhoin, 2007). Surface and subsurface fires at C&D landfills also pose a physical hazard to site employees.

The removal of drywall from the waste stream would reduce the potential of hydrogen sulfide generation from C&D facilities. Drywall recycling is an emerging market, and has the potential to significantly diminish the quantity of drywall going into C&D landfill facilities and reduce the potential of human health effects from exposure. Most drywall waste is generated from new construction (64%), followed by demolition (14%) (California Integrated Waste Management Board [CIWMB], 2008). Scrap from new construction is the primary focus of today's drywall recycling market, but future recycling strategies may also include recycling demolition drywall wastes (Townsend, 2003).

Weak regulations that govern C&D facilities at the state and local levels make addressing exposures at these sites an onerous and complicated process. Also, in the absence of a federal ambient air quality standard for hydrogen sulfide, many states have promulgated their own hydrogen sulfide standards—but others have not. Without these kinds of standards, requiring changes in facility operations that lead to reductions in community exposures is difficult at best.

The issues of national consistency and the potential for adverse effects on human health necessitate a dialogue about how best to manage C&D debris while minimizing its effects on neighboring communities. When health issues arise, it is challenging for some states to protect human health from the consequences of inadequate C&D management. Negative public health impacts would be avoided if more careful consideration was given to C&D landfill siting, design, management, and closure. Such an approach would protect health and quality of life for neighboring residents and employees.

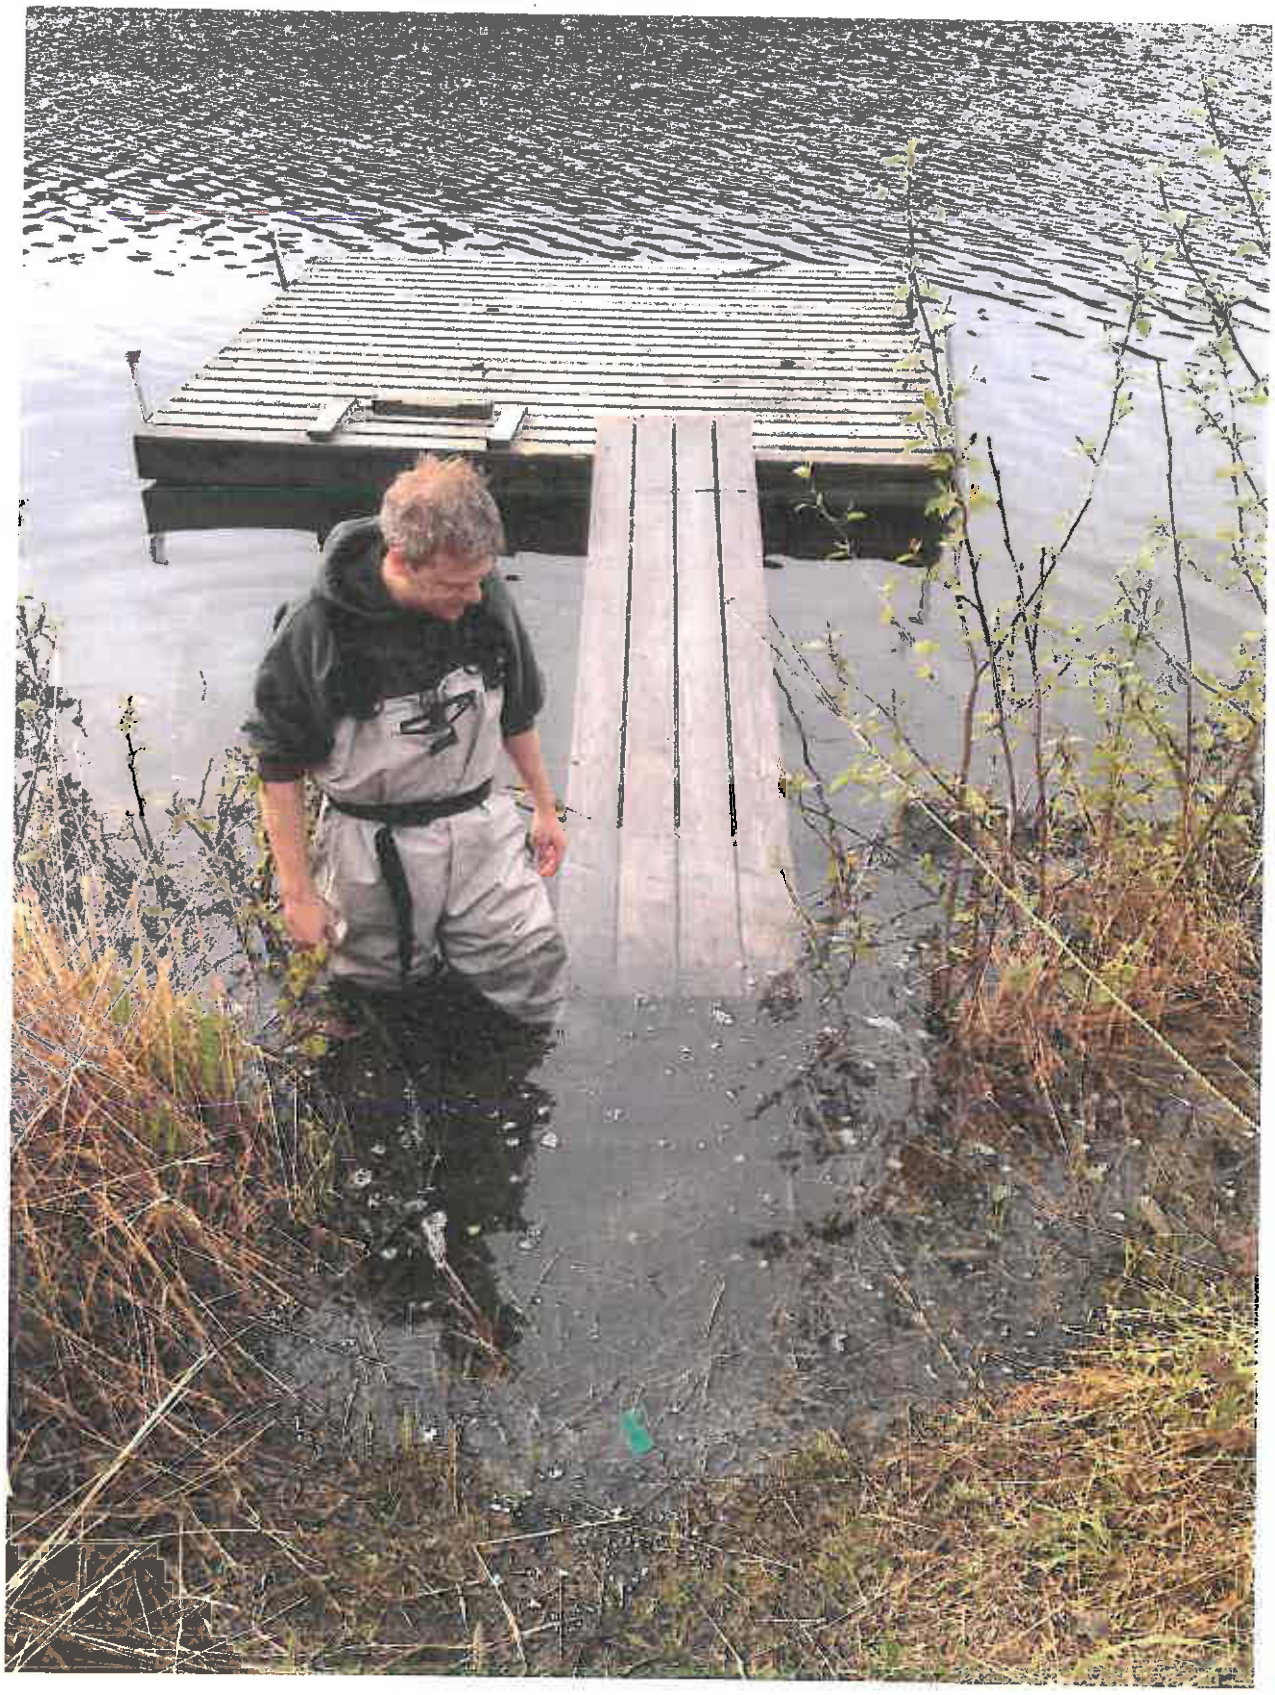
Subject: CMS MONOFILL COMMENTS: Resend

Hi Susan,

The file said they were under 10MB but looks like one of my emails got rejected so I am resending. Please confirm they came through.



RE: Comments on CMS proposed Monofill

From: Stephanie & Stephen Nowers, Canoe Lake Subdivision

Attachments:

- 2009 Ohio EPA report on C&D Landfills
- 2008 Hydrogen Sulfide report from US department of Health and Human Services
- Photos of 2013 rise in Canoe Lake caused by spillway on gravel pit property.
- Photos of illegal dumping on CMS' site and into pond

The Conditional Use Permit Request from Central Monofill Services should be denied because the monofill operation as proposed poses significant potential to harm public health, safety, and welfare. This proposal is essentially the same one CMS submitted last year, which the planning commission denied and the reasons for denial are still valid. CMS proposes no extra protections for their operation this time that would protect water and air quality and in fact has removed a groundwater monitoring plan from the application that would be a first line of detecting pollution.

MINIMAL ECONOMIC BENEFIT: The proposed monofill offers minimal economic benefit while posing significant risk to millions of dollars of residential property. CMS' application states they expect to create 3 full-time jobs and 30 periodic jobs. This is a drop in the bucket compared to the value of surrounding residential property, and the value of clean water. Of note as well is that the property tax revenue paid by CMS from its 118 acres is less than we pay on our single residential home on one-acre on nearby Canoe Lake. This operation does not provide an income stream for the borough or borough residents. And should contamination occur, it will almost certainly be the taxpayers – primarily borough property owners – who will be footing the bill not CMS. CMS appears to have limited insurance and bonding that looks to total about $10 million and perhaps as low as $5 million, according to their application and records filed with Alaska Department of Environmental Conservation.

POOR RECORD OF COMPLIANCE: The borough should take CMS's record in the borough into account in judging the promises made in this application.

CMS stresses in its application that proper management is the key to keeping pollution out of the monofill and that they have the appropriate controls in place to prevent pollution from taking place. However this has not been demonstrated by their record. In its short time so far in the borough, CMS has shown an inability to comply with state and local laws. This includes illegally dumping trash on the property in violation of borough code and refusing to clean it up until cited, found guilty in court and under threat from the Alaska Department of Environmental Conservation. This shows a lack of operational controls or a culture of disregard for state and local rules and regulations. And this is not even to note that the original dumping was done directly into a small pond, which is particularly difficult to fathom given the stress and importance placed on keeping material out of water. It begs the question of how well CMS is able to handle much more difficult tasks like screening out lead paint and arsenic-tainted wood. It is also a

particularly troubling given their desire to dispose of RACM asbestos at the site, and the high hazard to human health posed by not doing that with proper controls.

This company also repeatedly states in their application that this dump is not a hazard to the community because of the controls they have in place. Yet if one pulls the Federal Motor Carrier Safety Administration Safety Measurement System (SMS) for Central Environmental Inc (U.S. DOT#: 499480), one sees a company incapable of following basic vehicle maintenance requirements. According to the FMCSA, 73% of motor carriers in the same safety event group have better on-road performance than Central Environmental Inc.; the government's intervention threshold is 80%. CEI's vehicle out of service rate is 33%, compared with a national average of 21%.

I find one example from their SMS particularly telling. On March 14, 2014, a truck and trailer combination (FSH766 and 1666SK) were cited for six violations, including a violation for tread and/or sidewall separation and, more importantly, an out of service violation for an inoperative turn signal. One month later, on April 15, this same truck and trailer combination was cited for exactly the same violations. Maybe these are small safety issues but despite active enforcement, CEI either chose not to fix the equipment failures on their vehicles or did not have the personnel to do so. This same company is asking the residents of Palmer and the Mat-Su Borough to have faith in their safety processes and procedures.

CMS is also fighting complying with the Alaska Department of Natural Resources, which has told the company that a spillway installed between two of the gravel pit ponds is not operating as permitted. Instead of complying, CMS is fighting that request. ADNR has estimated the flow through the spillway at 1,000 gpm or 1.44 million gallons a day, a rate which has reduce somewhat since CMS attempted - against DNR recommendations - to stop the flow with a modification. This is within CMS's rights to contest DNR, but does not reflect well on the company's willingness to deal with issues on its property and the impacts it has off property.

THREAT TO WATER QUALITY: Multiple studies have shown that C&D landfills can leach carcinogens that pose threats to health and water quality. According to a 2009, Ohio EPA report (*see attached), the state tested 30 C&DD landfills. All 30 had at least 3 parameters that exceeded health or water quality standards. 29 of the 30 landfills had 8 or more parameters that exceeded health or water quality standards. In particular, they were concerned about "parameters that were found in C&DD leachate that were multiples of the health based standards (such as arsenic, boron, manganese, and lead), carcinogens (such as arsenic, vinyl chloride, and benzene), mobile in the environment (such as arsenic, vinyl chloride, and benzene), persistent in the environment (such as antimony and lead), or which bioaccumulate (such as arsenic, copper, lead, mercury, nickel, and zinc). Their conclusion was that "Leachate from Ohio C&DD landfills poses a threat to public health and the environment if released to ground water or surface water. The threat is posed by a variety of organic parameters, metals, and inorganic parameters. The degree of risk associated with the threat by a release is dependent upon how the C&DD was disposed, site conditions, and circumstances surrounding the site, which often change over time".

CMS states that "expert opinion indicates no risk to groundwater" from this operation.

But there is sufficient debate on this point. CMS does not offer any extra protections such as a liner or groundwater monitoring to take that uncertainty into account. As noted in reports by J.A. Munter in February and June 2014: "There are no significant barriers to the migration of this leachate into groundwater and it is highly likely to result in measurable increases in contaminants beneath the facility and for some distance downgradient." Of particular note is a lack of viable data on the seasonal high ground water. Munter notes that CMS reports fail to show the bottom of the waste will stay dry.

CMS does not appear to have a clear handle on the hydrology of this site. CMS gave assurances and stated in its original permit that they had at least 10 foot of clearance between monofill materials and groundwater. Now they state that clearance exists on only 70% of the proposed monofill site.

They also give assurances that they will not affect area wells. CMS correctly states that the Alaska DNR has not been able to corroborate the connection between the gravel pit ponds and area lakes and wells. However, this is not because it has been disproven. Rather DNR's past records were not well kept and DNR has stated there is a need for further study on the connectivity between the gravel pit ponds and area lakes and wells.

There is a long history of trouble controlling water on this property that has been well documented and makes the monofill site a particular risk to area water quality because of need to keep water out of the materials being dumped. The connection to area lakes and probable connection to area wells is a key concern. The furthest west pond on the Gravel pit property has affected water levels in Irene, Canoe and Bradley Lakes and when water levels have been raised in it, it causes a corresponding increase in the level of the lakes. It may also be connected to area wells, including ours. Alaska Department of Natural Resources is investigating this. The borough also has documentation of previous flooding events caused by water from this property all the way across the Glenn Highway.

In a report prepared for CMS by Ralph Hulbert, it notes that should contamination occur it is simple matter to hook up residents to the nearby water main of Palmer which runs close by. If that is the plan, then CMS should have bonding to pay for those hookups and the cost of providing city water to all the area residents.

As currently proposed, CMS' application has no groundwater monitoring plan. That is not acceptable given the particular concern about the hydrology on this property, the potential for toxins that can leach out of monofills, and CMS' record of showing an inability to comply with state and local regulations in the Mat-Su Borough.

CCA WOOD: CMS also does not address in its proposal the threat from Copper Chromated Arsenate (CCA) Wood waste. Although phased out in the early 2000s, this treated wood is common in older buildings. The EPA has recommended that when disposing of CCA treated wood that it be placed in landfills with a liner and leachate collection system. There is no accommodating for that in CMS' permit application. To see the EPA recommendation go to:
http://yosemite.epa.gov/osw/rcra.nsf/23e68e459512b15f85256bf000632213/5C5ADCDA1B27269985256E990071A68D/$file/14707.pdf

AIR QUALITY ISSUES: Drywall poses a significant risk to air quality and should not be allowed at the site because of the potential for release of hydrogen sulfide. A 2008

report from U.S. Agency for Toxic Substances and Disease Registry (ATSDR) (See Attachment), a federal public health agency of the U.S. Department of Health and Human Services, notes deaths from a hydrogen sulfide release at C&D landfill in Wisconsin and other reports of hydrogen sulfide levels being close to federally recommended levels for occupational exposure or in another case just below the federal standard considered immediately dangerous to life and health. The report concludes that "In recent years, however, it has become increasingly clear that emissions resulting from the decomposition of gypsum drywall and organic debris are a public health issue."

On Page 19 of the application, CMS states that surrounding residential property totals 16 acres. The graphic does not give a radius or definition of surrounding, but this seems to be underestimated. There are more than 16 acres of residential land just in Canoe Lake and multiple subdivisions nearby, including Crimosonview and Skyranch. In addition, this site is directly adjacent to the Kepler-Bradley lake system, which according to the state Department of Fish and Game is the 2nd most popular lake fishing area in the Mat-Su, 2nd only to Finger Lake.

No ADEC Approval: CMS does not have ADEC permit approval as stated repeatedly in their application.

Incompatible with future uses. CMS states this area will be useful for in the future as recreation land. The Asbestos they proposed to dump will have to be permanently marked. According to DEC regulations, "Drawings showing the boundaries of the RACM waste management area must be filed with the department and attached to the property deed, with a written warning about health and safety hazards related to disturbing the site."

Screening and buffers. According to the Alaska Department of Transportation, the Glenn Highway expansion could take as much as 20 feet of the berm currently screening CMS's property. This will reduce the current berms to about 10 feet high along the highway. That would leave up to 20 feet of cell sticking up above the berm adjacent to the highway, according to the information supplied in CMS' application.

There are setback requirements from the property edge. Given that DOT may condemn some of the CMS property for the highway expansion, has CMS taken this into account in their cell construction? Currently it looks like they plan to start in the cells nearest the highway including the proposed asbestos cell. A prudent move would be to keep these cells far enough away from the highway to not be affected when the state DOT expands the highway.

Gravel Operations: CMS states they plan to continue gravelling. But their application states 66 acres of the property is water with the remaining 52 acres slated for the monofill operation. Where do they intend to gravel on the site. If they do not, they should comply with the reclamation requirements for this site.

Executive Summary

In 2005, the Ohio General Assembly required Ohio EPA to revise its construction and demolition debris disposal regulations. The agency published draft regulations in 2006 and received extensive comments from stakeholders and other interested parties. In response to comments received, Ohio EPA conducted additional technical studies, including an evaluation of leachate data from Ohio's C&DD landfills. In 2007, Ohio EPA also sampled all of the operating C&DD landfills and one closed C&DD landfill in Ohio where access to Leachate existed (30 C&DD landfills). There are 56 licensed C&DD landfills in Ohio.

The conclusions of this report are as follows:

Ohio C&DD leachate contains a wide variety of inorganic parameters including heavy metals, light metals, trace elements, and other ions. It also contains a wide variety of organic parameters including pesticides, chlorinated solvents, non-chlorinated solvents, gasoline, substituted benzenes, phenolics, chlorofluorocarbons, polycyclic aromatic hydrocarbons (PAHs), phthalates, substituted alkanes, and alcohol.

The leachate from all 30 C&DD landfills had from 3 to 29 parameters with concentrations that exceeded health based standards, surface water quality standards, or both. The median was 12.5 parameters exceeding the standards. The leachate from 29 of the 30 C&DD landfills had eight or more parameters that exceeded the standards.

The wide variety of parameters detected in C&DD leachate, the wide variation in the number of parameters that exceeded health based standards and surface water quality standards in C&DD leachate and the magnitude of the exceedances are evidence that C&DD is not harmless or inert.

There are numerous parameters that were often detected in Ohio C&DD leachate of sufficient concentration that would violate discharge limits of Ohio rules if released to ground water or surface water. They could also cause or contribute to water pollution, and could adversely impact downgradient or downstream residential and public drinking water supplies. Of particular concern are those parameters that were found in C&DD leachate that were multiples of the health based standards (such as arsenic, boron, manganese, and lead), carcinogens (such as arsenic, vinyl chloride, and benzene), mobile in the environment (such as arsenic, vinyl chloride, and benzene), persistent in the environment (such as antimony and lead), or which bioaccumulate (such as arsenic, copper, lead, mercury, nickel, and zinc).

The concentrations of the parameters in Ohio C&DD leachate exceeded secondary maximum concentration limits (SMCLs) to the extent that discharge of the leachate with the average concentrations could render good quality ground water objectionable or unusable for consumption, washing, and industrial production.

Leachate from Ohio C&DD landfills poses a threat to public health and the environment if released to ground water or surface water. The threat is posed by a variety of organic parameters, metals, and inorganic parameters. The degree of risk associated with the threat by a release is dependent upon how the C&DD was disposed, site conditions, and circumstances surrounding the site, which often change over time. This conclusion is supported by numerous studies showing that impacts by C&DD landfills to surface water and ground water have occurred or were indicated (US EPA, Draft 1995b), (Hamilton County General Health District, 2001), (Ohio EPA, 2006), (Townsend, Jambeck, & Clark, 2002), and (Ohio EPA, 2008).

This information should be taken into account by the regulated community, citizens, legislators, and regulators when developing public policy and rules for the management of C&DD and the permitting, construction, operation, closure, and post closure care of C&DD landfills.

Synopsis of the Ohio C&DD Leachate Analytical Data

The conclusions stated on the previous page are supported by the following observations:

- Of the 30 C&DD landfills that had leachate sampled:
  - Each landfill had 3 to 29 parameters that exceeded health based standards for toxicity or carcinogenicity, surface water quality standards, or both.
  - The median number of parameters exceeding standards was 12.5.
  - 29 of the landfills had eight or more parameters that exceeded standards.

- Of the 273 parameters analyzed in the leachate at each landfill:
  - 95 parameters were detected at one or more C&DD landfill.
  - 79 parameters were detected at two or more C&DD landfills.

- Of the parameters detected in C&DD leachate:
  - 30 were chlorinated solvents and pesticides.
  - 25 were heavy metals, light metals, and trace elements.
  - 7 were non-chlorinated solvents.
  - 7 were other ions.
  - 5 were gasoline components.
  - 5 were substituted benzenes.
  - 4 were phenolics.
  - 2 were chlorofluorocarbons.
  - 2 were polycyclic aromatic hydrocarbons (PAHs).
